## Abstract

We examine the relationship between immigration and attitudes to redistribution by assembling a new dataset of immigrant stocks at the regional level in 140 regions of 16 Western European countries. We combine census and population register records with attitudinal data from the biannual 2002-2014 rounds of the European Social Survey. This data allows us to estimate this relationship by exploiting within-country variations in the share of immigrants across regions and by holding constant welfare policies set at the national level. We find that, relative to other co-nationals, native Europeans have lower support for redistribution when the share of immigrants in their region of residence is higher. This negative relationship between immigration and redistribution is robust to the inclusion of a rich set of regional and individual controls, as well as to using six alternative measures of preferences for redistribution. This negative correlation is confined to self-reported right-wing respondents while the preferences of left-leaning ones remain unaffected by the level of immigration. While immigration from EU15 countries have no detectable effects, immigration from non-European countries is strongly associated with lower support for redistribution. Results suggest the more culturally distant and the poorer are the immigrants, the stronger is the anti-redistribution effect on natives.

*Keywords:* Income redistribution, ethnic heterogeneity, immigration

# 1 Introduction

Public generosity, (as well as trust, and cooperative behavior ) travel more easily within the same ethnic lines, nationality and religious affiliation .<sup>1</sup> This is why redistributive policies are *ceteris paribus* more extensive in more homogenous societies. For instance, Alesina and Glaeser (2004) argue that one of the reasons why the welfare state is more generous and expensive in Western Europe than in the US is that European countries have been traditionally much more homogeneous than the US, a country built by relative recent immigrants. However in the last two decades or so immigration in Western Europe has exploded and has become (and will remain for the foreseeable future) one of the major political issue in this region. Given that European countries have become less homogenous, has there a reaction against the welfare state in the native populations ?

The answer provided by this paper is "yes", with qualifications and heterogeneous effects.

One difficulty in analyzing the effect of immigration on welfare policies is the self selection of immigrants. The latter (especially the poorest) may be attracted by the so called "welfare magnets". How this effect may bias the results is not obvious: immigrants may indeed flow to countries with more generous welfare systems but these are precisely the countries in which individuals feel more favorably towards welfare so the direction of the bias is unclear.<sup>2</sup> In this paper we use a newly assembled dataset in which we consider regional data on the distribution of immigrants in 16 countries in Europe with 140 regions. Therefore we can have country fixed effects, in other words we can hold constant welfare policies at the national level and we can examine different reactions of different natives living in different regions of their country. We cannot hold constant welfare policies which vary at the local level an issue

---

<sup>1</sup>For a survey on the literature on redistributive policies see Alesina and Giuliano (2014) for a survey on the effect of heterogeneity on social capital and trust see Alesina and La Ferrara (2005) and for recent results Algan et. al. (2017)

<sup>2</sup>Immigration flows are well known to be affected by the extent of the welfare state in receiving countries (Borjas, 1999, Grogger and Hanson, 2011). Besides this issue of reverse causality, idiosyncratic differences *between* countries (e.g. in terms of average incomes, extent of redistribution) further complicate a purely descriptive analysis. Endogeneity is also prevalent *within* countries, as immigrants' select into different occupations and people's average preferences vary by the type of occupation they pursue (Guillaud, 2011). For example, immigrants sort into manually-intensive occupations where they may have comparative advantages (vis-a-vis natives), but the average native worker in these occupations - irrespective of immigration - tends to favor more redistribution (since he is a net recipient of transfers).

which may be of limited importance in some countries ( e.g. France) but more relevant others (e.g. Sweden). For our measure of preferences we use the European Social Survey (ESS) from 2002 to 2014.

The effect of immigration on preferences for redistribution is not homogenous across countries. It is stronger in Scandinavian countries (Finland Norway, Sweden) the Netherlands and in France . It is weaker or non existent in other countries. We also find that in every country the effect of immigration on preferences for redistribution holds for self reported right leaning respondents. Immigrants from different origin countries have different effects on natives' attitudes. While immigration from other European countries within the EU15 seems to have no effect, immigration from East-Europe is associated with a decline in natives' support for redistribution. However it is the immigration from countries outside Europe (mainly from Africa and Asia) which has the strongest negative effect. Thus the "distance" in terms culture, genetics etc. from the natives is relevant in determine reaction to immigrants. Finally, it is not only the more recent immigration (newcomers arrived less than 10 years ago) that is associated with a lower support for redistribution, but also the more ancient immigration (migrants arrived more than 10 years ago) seems to reduce pro-redistribution attitudes.

Our paper is related to the literature of the demand for redistribution. The latter depends two factors: First, if the individual thinks she benefits from an income transfer scheme and second, if she regards the other beneficiaries of the scheme to be worthy recipients of support.<sup>3</sup> The second aspect is especially relevant of our purposes Cultural beliefs about who is a worthy recipient of public generosity correlate with race, especially in the United States. In many studies, representatives of the (white) American majority are found to be much less supportive of redistribution than members of minority groups (Alesina and La Ferrara, 2005). This is typically interpreted not only as heterogeneity in cultural preferences, but as sign of racial prejudices. Using individual data for the U.S., Luttmer (2001) shows evidence for "group loyalty effects", namely that support for redistribution increases if members of the respondent's own ethnic group are over-represented among welfare recipients. Using experimental data, Luttmer and Fong (2009) study actual self-reported attitudes as well as charitable giving in a dictator game (where respondents choose which

---

<sup>3</sup>For a survey of the literature, see Alesina and Giuliano (2010) and Stichnoth and Van der Straeten (2013).

fraction of income to allocate to a charity dedicated to Hurricane Katrina victims). The authors find no direct effect of race (of respondent or victim O presented in the experiments) in the experimental setting, but do so for people who identify strongly as whites or blacks. Alesina, Baqir and Easterly (1999) show that U.S. cities and metropolitan areas with higher racial heterogeneity provide fewer productive public goods (e.g. public schools). Alesina, Baqir and Hoxby (2004) demonstrate that U.S. jurisdictions form endogenously in response to a trade-off between scale benefits and costs of racial heterogeneity. Using data on welfare spending for families with dependent children, Alesina and Glaeser (2004) show that the share of African-Americans in the population correlates highly negatively with maximum welfare allowances across U.S. states. These empirical studies for the U.S. have in common that they find racial, not ethnic, linguistic or birthplace differences, to be the politically salient margin with respect to attitudes and welfare spending.

With more specific reference to immigration, in the US, Tabellini (2017) finds results for the US regarding the great migration in the first part of the last century which are fully consistent with those of the present paper. Natives became less favorable to social policies in cities which received more immigrants particularly those culturally or religiously further away from the natives. These effects hold despite the economic benefits for the natives brought by the immigrants.

Empirical evidence for other countries is sparse. For Canada, Soroka et al. (2006) analyze community surveys and find that a comprehensive measure of diversity (racial, ethnic and birthplace differences) correlates negatively with trust, but find only very weak evidence for attitudes to redistribution. For Europe, Senik, Stichnoth and van der Straeten (2009) use European Social Survey data for 22 countries and find only a weakly negative link between people's perception of immigrants' presence and attitudes. This link grows stronger for people who express a dislike of immigrants and are concerned about the economic effects of immigration. Finseraas (2009) finds that people who perceive the presence of immigrants to be welfare state burden are also less open to redistribution in general. Magni-Berton (2013) finds that immigration affects attitudes not via xenophobia or group loyalties, but via labor market concerns. All these studies use survey-based attitudes perceptions towards immigrants to infer on the effect of immigration on redistribution, not actual levels of immigration. Burgoon, Koster and Egmond (2012) show that the effect of immigration on attitudes can even be positive at the occupational level. Also using European Social Survey

data, Burgoon (2014) finds that the national level link between immigration and attitudes is mediated by the degree of economic integration (e.g. dependency on unemployment benefits).<sup>4</sup>

For Germany, Stichnoth (2012) tests a similar hypothesis using socioeconomic panel data for 1997 and 2002. He finds only weak evidence for a link between regional differences in terms of immigrants' employment status and attitudes to redistribution in Germany. For Sweden, Dahlberg, Edmark and Lundquist (2012) use exogenous variation in refugee placement in the late 1980s and early 1990s and find a strongly negative causal relationship between the share of (non-OECD) foreigners in Swedish municipalities and attitudes to redistribution.

The paper is organized as follows. The next section describes in detail our data set which is by itself a contribution of the paper. Section 3 presents our main specification and exogeneity assumptions. Section 4 describes our main results including heterogeneous effects. Section 5 describes robustness checks and the last section concludes.

## 2 Data

The first contribution of this paper is to construct a novel dataset of immigrant stocks at the regional level in 16 different western European countries. While there have been several efforts to compile global bilateral migrant stocks across countries (e.g. Docquier et al., 2009; Ozden et al., 2001 ), we provide, for the first time, a dataset of immigrant population by origin country and by educational level in each region (NUTS) of Europe by harmonizing population censuses and registers in the years 1991, 2001 and 2011. When then combine this dataset with individual attitudinal data drawn from the European Social Survey across more than 140 regions in western Europe.

### 2.1 Immigrant stocks at the regional level

#### Primary sources of data.

To obtain immigrant stock data by origin country and region of destination in European countries, we mainly draw on population census data, from the 1991, 2001 and 2011 round of censuses – see table ???. Census data were used for 10 countries, either provided by the

---

<sup>4</sup>To isolate country level variables, these studies assume those latent variables to be orthogonal to other covariates and rely on random intercept models.

national statistical offices, or taken from IPUMS International : Austria, Belgium, Ireland, Italy, France, Greece, Portugal, Spain, Switzerland, and the United Kingdom. <sup>5</sup> Countries not taking periodic censuses but keeping population registers have provided data extracted from these registers. This is the case for 6 countries: Denmark, Finland, Germany, Norway, the Netherlands and Sweden. To obtain migrant stock data by educational level, we sometime rely on Labor Force Survey instead (due to the lack of suitable census data)– see table ?? <sup>6</sup>

Official records usually apply two different definitions of what constitutes an international migrant: either being born in a foreign country or being a citizen of a foreign country. When harmonizing the data, we give priority to the definition based on country of birth. We compile the immigrant stock data in the regions of residence of the 16 European countries we cover by using the NUTS geocode standard for referencing the subdivisions of countries. The NUTS standard – developed and regulated by the European Union since the 1970s – defines minimum and maximum population thresholds for the size of the NUTS regions: between 3 and 7 millions for NUTS1 units, between 800,000 and 2 millions for NUTS2 units, and between 150,000 and 800,000 for NUTS3 units. NUTS regions are generally based on existing national administrative subdivisions. For example in mainland France, NUTS1 mirrors the 9 French areas "Zones d'études et d'aménagement du territoire" while the NUTS2 corresponds to the 22 French "Regions" and NUTS3 to the 96 French "Departements".

### Harmonizing the data

**Definition of migrants** We measure immigration on the basis of country of birth (as opposed to citizenship). Birthplace data is readily available from most of the primary sources, except for the 1991 rounds of the Austrian and Greek censuses, as well as for the 1991 and 2001 rounds of the German registers. In order to have a consistent definition of immigrants over time and comparable across countries, we choose to impute the number of foreign-born in the few instances in which data is missing. We follow the approach of Brucker et al (2013) by using the ratio between foreign citizens and foreign-born in year  $t$  in order to infer the

---

<sup>5</sup>For the UK, the census data we used (as provided by the ONS) does not cover Scotland nor Northern Ireland. Those two countries run separately their own census which we could not have access to

<sup>6</sup>We use the European Labor Force Survey (ELFS) instead of population censuses in three countries: Belgium, Switzerland and Germany. In Belgium and Switzerland, we chose not rely on census data because of the high share of foreign-born with unknown level of education. In Germany, the census does not report the birthplace, only the Labor Force Survey does.

number of foreign born in the previous years  $t - 10$  or  $t - 20$ .<sup>7</sup>

**Aggregation of origin countries** Following the end of the cold war, many countries redrew their political boundaries, with some fragmenting into smaller nation states, such as the Soviet Union or Yugoslavia. The coding of birthplace data, which varies from one population census to another, often only reports the original territory as it existed before the split into newly constituted countries. For example, in many censuses of the 16 European countries, Serbia and Croatia are aggregated under the name of the former Yugoslavia. The same applies to the former USSR. To produce a consistent list of countries of birth across receiving countries and for the entire timeframe of the database, some adjustments had to be made. We treated as a single entity the countries that belonged to each of the following territory : the former Yugoslavia, the former Czechoslovakia, the Netherland Antilles, the Channel Islands, Sudan and South Sudan, Indonesia and East Timor. With respect to the ex-USSR, we choose to impute (when not known) the number of immigrants originating from the individual countries that comprise that area. Observing the total number of migrants from USSR in a given destination regions, we allocated these migrants to each individual countries by using the IAB brain-drain database (Brucker et al.,2013) which provides, at the national level, the number of immigrants by individual origin country in 1991, 2001 and 2011.<sup>8</sup> After harmonization, 217 different places of origin (mostly individual countries) are

---

<sup>7</sup>In practice we impute the number  $\widehat{N}_{r,o,t}$  of foreign-born from origin country  $o$  living in region  $r$  at time  $t$  by using the observed number of foreign citizen  $C_{r,o,t}$  in the same year, region and coming from the same origin country:

$$\widehat{N}_{r,o,t} = r_{o,t+10} * C_{r,o,t}$$

with  $r_{o,t+10} = \frac{N_{o,t+10}}{C_{o,t+10}}$  the ratio at time  $t + 10$  between national-level number of foreign-born and foreign-citizen from origin  $o$  and living in the same destination country of region  $r$ . For Austria and Greece, we impute the number of foreign-born in 1991 by using the ratio between foreign-born and foreign-citizen in 2001. For Germany, we impute the number of foreign-born in 1991 and 2001 by using the ratio in 2011. In order to assess the precision of such imputation, we predicted the number of foreign in Austria and Greece in 2000 following the same approach (i.e. using the 2011 ratio between foreign-born and foreign-citizen) and compared the imputed 2000 values and the observed 2000 values of foreign-born by origin country and region of residence. In both Austria and Greece, we obtain a coefficient of correlation above 0.97 between the observed and the imputed values. For Germany, we checked how the 2000 imputed value by origin countries correlate with the DIOC data 2000 values at the national level (Docquier et al., 2006). Considering only origin countries with positive DIOC numbers of migrants, we obtain a coefficient of correlation above 0.96 – and in particular a similar number of migrants from the ex-USSR, the so-called ethnic Germans.

<sup>8</sup>For example, for a given year and destination region, we impute the number of Polish migrants by

distinguished in both 1991, 2001 and 2011. Regarding missing information on the place of birth, the share of the population for whom the place of birth is missing or too imprecise is below 1% for most receiving countries and not higher than 4% for some countries (UK and Switzerland).

**Education data** We distinguish three levels of education using the the International Standard Classification of Education primary: primary (ISCED 0/1/2, i.e. lower secondary, primary and no schooling); secondary (ISCED 3/4 : high-school leaving certificate or equivalent) and tertiary education (ISCED 5A/5B/6 or higher).

## 2.2 Individual attitudinal data

Data on individual attitudes towards redistribution is taken from the European Social Survey (ESS). The ESS is the largest such survey and contains information on a wide range of socioeconomic and political values for individuals in 28 European countries. Data is available for seven biannual survey waves starting in 2002 and has been widely used in the study of preferences (see e.g. Card, Dustmann, Preston, 2005 or Ortega and Polavieja, 2012). To assess preferences to redistribution, we rely on answers to the statement “*The government should take measures to reduce differences in income levels*”. We use a 5-point scale variable that measures the extent to which the respondent agrees with the previous statement : agrees strongly (5), agrees (4) , neither agree nor disagree (3), disagree (2), disagree strongly (1)

## 2.3 Matched data on attitudes and immigrant stocks

**Combining the data at the regional level** The ESS provides relatively precise information on the place of residence of the respondents: at the regional NUTS2 level for most countries except for Belgium, France, Germany and the UK for which only larger NUTS 1 regions are available. In Ireland, smaller NUTS 3 region are available. In few instances the coding of the place of residence in the ESS data does not fully coincide with the NUTS classification or is sometimes inconsistent across the different survey rounds. To address this issue, we aggregate different NUTS regions into one larger unit : the northwestern re-

---

multiplying the number of migrants from the USSR in the same year and destination region with the share of Poles among all URSS migrants in the same year and destination country, as provided by the IAB dataset.

gion of Switzerland with Zurich (CH03-CH04) , the Southern part of Finland with Helsinki (FI1B-FI1C), and the Trentino province with the Bolzano province in Italy (ITH1-ITH2). Moreover, some of the NUTS regions are poorly covered by the ESS survey (with typically less than ten respondents) and we decided to exclude them all together. This is the case of the regions of Ceuta and Melilla in Spain, the Acores and Madeira in Portugal, Aland in Finland, and Molise and the Valle d’Aosta in Italy.

Once these small adjustments are made, we are able to successfully combine the ESS attitudinal survey with the immigrant stocks data across 148 different regions of residence – either NUTS2 or NUTS1 – in the 16 European countries we cover over the period 2002-2014. Table ?? in Appendix provides the exhaustive list of NUTS regions included in the analysis. Since we aim at measuring individual exposure to immigrant’s presence, we only use rounds of the ESS that are close enough to the time at which immigrant stocks are measured. In practice we chose to use ESS rounds carried out no later than four years after the rounds of population censuses and registers. We thus merge the 2002 and 2004 rounds of the ESS to the immigrant stocks in the 2001 round of censuses/registers, as well as the 2010, 2012 and 2014 rounds of the ESS to the immigrant stocks in the 2011 round of censuses/registers.

**Estimation sample** Since we are interested in the effect of immigration on natives’ demand for redistribution, we restrict the ESS sample to native-born individuals, i.e. born in their current European country of residence. Furthermore, given its very particular history, we exclude individuals living in East Germany, notably because of the well-documented persistence of strong preferences for redistribution in the former GDR (Alesina and Fuchs-Schndeln, 2007). Pooling the 2002, 2004, 2010, 2012 and 2014 rounds of ESS, we obtain a repeated cross section that contains immigrant stock data for 142 different regions in 16 countries and attitudes towards redistribution for 124,402 individuals living in these regions. There are on average 876 respondents by region, with a minimum of 43 respondents in the Italian region of Friuli-Venezia (ITH4) and a maximum of 4991 in the Belgium Flemish region (BE2).

## 2.4 Descriptive Statistics (incomplete)

Table ?? provides some descriptive statistics of the two main variables used in the analysis : the preferences for redistribution measured with a 5-point scale and the share of immigrants (foreign-born) in the population at the regional level. In the estimation sample, the average of attitudes in favor of redistribution is 3.79 and the average share of immigrants is 11% . The distribution of attitudes in favor for redistribution is clearly skewed to the right, with a mean well above the median. In all countries, a majority of individuals “agrees” or “strongly agrees” with the statement. Countries with lowest overall preference for reduction in income differences (share of population that at least “agrees”) are – among others – Denmark , the Netherlands and Great Britain. Most in favor of lower income inequality are – among others – Portugal, Spain, Italy, France and Greece (0.90).<sup>9</sup> This pattern serves as reminder that attitudes to redistribution are a good proxy for a country’s position on many policy related questions. Descriptive statistics for all other individual socioeconomic variables we extract from ESS can be found in the appendix.

Although there are some differences in the average support for redistribution across coun-

<sup>9</sup>Interestingly, the Scandinavian countries mostly lie below the European average, suggesting that respondents take the prevailing level of redistribution into account.

tries, these differences are not very pronounced, ranging for 2.99 in Denmark to 4.32 in Greece. Attitudes mostly vary across individuals living in the same region, with the inter-regional variation only explaining 12% of the total variance of individual attitudes. The fact that attitudes vary mostly within region is also true for each European country, where the inter-regional variation generally explain no more than 5 or 6% of the total variance.

### 3 Empirical specification (preliminary)

We estimate the following linear model for native-born individual  $i$ , living in the region  $n$  of country  $c$  at survey round  $t$ , with  $t = 2002, 2004, 2010, 2012$  :

$$y_{inct} = Mig_{nt}\beta + X_{it}\alpha + Z_{nt}\lambda + \delta_{ct} + \epsilon_{int} \quad (1)$$

where  $y_{int}$  is the 5-point scale variable measuring natives' support redistribution as described in the data section above.  $Mig_{nt}$  is the log share of foreign-born in the total pop-

ulation of region  $n$  sometime before year  $t$ . For the ESS rounds 2002 and 2004 we use the immigrant stock in the 2000 population census. For the ESS rounds 2010 to 2014, we use the immigrant stock in the 2010 population census. In all specifications, we include a set of country-year fixed effect  $\delta_{ct}$ . The vector  $Z_{nt}$  includes controls at the regional level such as the native population (log), GDP per capita (log), unemployment rate, and the share of tertiary educated among the native population. The vector  $X_{it}$  controls for individual socio-demographic characteristics, such as the respondent’s sex, age, education, main activity during the week before the interview, the size of her household, her parent’s education and parent’s immigration background, as well as her usual place of residence. I cluster standard errors at the region-by-year level to account for the possible correlation of the individual-level residuals  $\epsilon_{int}$  within the same region and year.

## 4 Results (preliminary)

### 4.1 Basic Specification

Table ?? shows the correlation between the share of immigrants in the population at the regional level and the natives’ attitudes towards redistribution. We include country-year fixed effects in order to control for average difference in attitudes across country and over time. Hence, estimates are obtained by comparing attitudes of co-nationals within the same country and the same year, but living in different regions and thus differently exposed to the presence of immigrants. Table ?? reveals that the negative association between the share of foreign-born and natives’ attitudes is robust to the inclusion of regional controls (column 2), to the inclusion of individual socio-demographic controls (column 4), to the inclusion of respondent’s last occupation and household income (column 5), as well as to the inclusion of individual political affiliation (rightist or leftist) , measures of altruism, inequality aversion and sense of fairness (column 6). Estimates are also robust to excluding the capital regions of each of the 16 countries as column 3 shows <sup>10</sup>.

When the full list of controls is included in column 6, we obtain a highly statistically significant coefficient of -0.070. This estimates suggests that a one-standard increase in the log share of immigrants (0.61) reduces natives’ support for redistribution by .042, which

---

<sup>10</sup>For Spain, both regions of Madrid and Barcelona are excluded. In Italy, both regions of Milano and Roma are excluded

represents a 1.1% decline with respect to the baseline average support. Since by construction the share of immigrants at the regional level can only explain variation in attitudes across regions and not within, it seems more natural to compare the effects of immigration to the typical cross-regional variation in attitudes – rather than to the overall variation, which encompasses within-region variation on which our model has nothing to say ( and which is much larger than smaller magnitude than cross-regional variation). Thus, an one-standard-deviation increase in the share of immigrants is associated with a decline by a 11.8% of the cross-regional standard-deviation of natives’ attitudes.

Table ?? presents the estimates of same correlation between immigrants’ share and natives’ attitudes obtained by using an alternative specification which does not include country fixed effects ( but only year fixed effects). Estimates are thus obtained using variation of attitudes and immigrants’ share across country, and no longer within country only. As table ?? shows, the correlation becomes very weak and statistically insignificant when country fixed effects are no more included. This suggests that reverse causality might drive the estimates when cross-countries differences are not controlled for : the relative generosity of the national welfare state is a well-know pull factor attracting immigrants and may thus generate an upward biases in the cross-country OLS estimates (welfare magnet hypothesis; Razin and Wahba, 2015).

## 4.2 Heterogeneous effects depending on receiving country

Table ?? explores how the effect of immigration varies across the different countries of destination. The estimates shows the correlation between the immigrants’ share and natives’ attitudes within each country of residence of the respondents (estimated using variations across regions). Table ?? reveals that the negative association between the immigrants’ share and an natives’ attitudes holds within specific countries only and is absent in the other European countries. It seems that the presence of immigrants lowers the support for redistribution exclusively among native citizen of France, the Netherlands, Norway, Finland and Sweden. The last column (7) presents the size of the estimated correlation in terms of cross-regional standard-deviation elasticity. For instance, in France, a one-standard-deviation increase in the log share of immigrants is associated with a education by 36.2% of the cross-regional standard-deviation in natives’ preferences for redistribution. In Sweden, this elasticity is estimated to be as high as 45%.

Regional controls include: native population (log), GDP per capita (log), unemployment rate, share of tertiary educated among the native population. Individual Controls include: year of birth\*sex , sex\*education, household composition, employment status (unemployed, self-employed, retired.), education of parents and country of birth of parents, type of respondent's domicile (big city, suburbs, small town, village) . Individual income controls include: current or former occupation (isco88 2 digits), household income quantile in the country, and feeling about current household's income. Ideology controls include: Placement on left right scale, opinions about whether people should be treated equally and have equal opportunities, opinions about the importance to help people and care for others well-being, opinions about whether Most people try to take advantage of you, or try to be fair.

Standard errors are clustered at the NUTS- year level

### 4.3 Heterogeneous effects depending on native individuals' characteristics

Table ?? explores how the effect of immigration depends on native individuals' characteristics. The specification allows the association between immigrants' share and natives' attitudes to be a function of the educational attainment of the respondent (primary, secondary or tertiary) , of the household income, the type of domicile (big city versus suburb or small town or village), the political affiliation (rightist versus leftist) , the aversion to inequality, and the attitudes towards immigrants. Table ?? reveals that the negative effects of immigration on support for redistribution is more pronounced among most educated natives (tertiary versus primary educated natives) and among richest households (in the last income quintile as opposed to the first three quintile), and is slightly less pronounced in big cities. These results are reasonable: the immigrants are poorer than average natives thus rich natives feel that they would bear a disproportionate burden of welfare policies directed towards immigrants. Also in big cities people may become more used to interacting with immigrants. Think of London versus the rest of England.

The most notable dimension along which the effect of immigration is heterogeneous is political affiliation : the effect on pro-redistribution attitudes is nearly three times more negative among rightist natives (column 5) than among the entire sample (column 1), while being zero among leftist natives. Rightist natives being generally less averse to inequality and holding negative views on the cultural effects of immigration, the results evidenced in column 6 and 7 are to be expected : immigration lowers pro-redistribution attitudes mostly among natives with lower aversion to inequality and among those considering that immigrants make the country a worse place to live in.<sup>11</sup>

In Table ?? column 2 , 3 and 4 suggest that the differential effect of immigration across political affiliation survives and remains unchanged when we allow immigration to have differential effects also across the educational level of respondents and their household income. Thus that the differential response of rightist and leftist natives cannot be accounted for by differences in education or income. By contrast, the heterogeneity of response across educational and income level seems of a much lower magnitude relative to – and almost fully explained by– the heterogeneity across political affiliation (column 4).

---

<sup>11</sup>Alesina et al. (2018) report as well very strong heterogeneous effects between right and left wing respondents in surveys relating redistribution and perception of social mobility

All variable which is interacted with the log share of immigrants is included in the controls of the regression, as well as its interaction with country-year fixed effects. This allows to control for difference in attitudes in a flexible way. This specification estimates the parameters of interest using cross-regional variation in attitudes of co-nationals in the same year and who share the same characteristics of interest (education , household income, rightist or leftist..). "domicile: big city" is a binary equal one if the respondent says to live in a big city as opposed to the suburbs, a small town or a village on the countryside. "rightist respondent " is a binary equal one if the respondent places himself on the right of the political spectrum (6 to 10 scores on a 11 point scale). "respondent with low aversion for inequality" is a binary equal one if the respondent does not strongly agree with the statement that people should be treated equally and have equal opportunities. "respondent think immigrants make the country a worse place to live" is a binary equal one if the respondent agrees with that statement (score ranges from 0 to 5 on a 11 point scale)

All variable which is interacted with the log share of immigrants is included in the controls of the regression, as well as its interaction with country-year fixed effects. This allows to control for difference in attitudes in a flexible way. This specification estimates the parameters of interest using only variation in attitudes of co-nationals in the same year who share the same characteristics of interest (education , household income, rightist or leftist..). " *rightist respondent* " is a binary equal one if the respondent places himself on the right of the political spectrum (6 to 10 scores on a 11 point scale) .

#### 4.4 Heterogeneous effects depending on immigrant’s country of origin and immigrants’ skills

Table ?? investigates whether the effects of immigration depends on the countries of origin and skills of the migrants. We focus on the sample of countries for which we find evidence of a significant negative correlation between immigration and attitudes to redistribution, i.e. France, Netherlands, Norway, Sweden, Finland. Furthermore, we restrict the sample to rightist natives since immigration does not seem to affects preferences of leftist natives.

Immigrants from different origin countries seem to generate different effects on natives’ attitudes. While immigration from EU15 countries is not significantly associated with changes in natives’ attitudes (column 2), immigration from East-Europe is associated with a decline in the support for redistribution (column 3). But it is most importantly the immigration from countries outside Europe (mainly from Africa and Asia) which has the strongest negative effect (column 4). When we simultaneously include the three types of immigrants’ origin in the regression (column 4), it appears that it is immigrants from countries outside Europe to completely drive the average negative correlation between immigration and natives’ attitudes, as estimated in column 1. The next columns 6-9 suggest that immigrants from poorer countries (with a GDP per capita below the median of all origin countries) have a more negative effect on natives’ attitudes relative to immigrants from richer countries. When both type of immigration are included, we find a significant difference between the effects of immigration from rich origin countries relative to poor origin countries This difference remains (in terms of point estimates but not of statistical significance) when we control for the share of EU15 immigrants. This suggests that non-European migrants who more likely to be net consumer of the welfare system of destination (i.e. to represent a fiscal burden) or to be low-skilled reduce natives’ support for redistribution by a larger extent relative to other non-European immigrants However, when looking at the differential effects of immigrants depending on their education level (primary, secondary or tertiary education), we do not find any significant differences (column 10-13).

Table ?? examines whether the effects of immigration depends on how long the migrants have been living in the host country (i.e. time since arrival). The first column estimates the effects of immigrants 10 years before natives’ attitudes are measured in the European Social Survey. We hence match 1990 immigrant stock data (drawn from 1990 population census) with attitudes elicited in the 2000s, and match 2000 immigrant stock data with

attitudes elicited in the 2010s. Column 2 includes both the immigrants' share 10 years ago and the inflow of migrants during the last decade, obtained by the variation over time in the immigrants's share between the beginning and the end of the decade. Table ?? suggests that it is not only the more recent immigration (newcomers arrived less than 10 years ago) that is associated with a lower support fo redistribution , but also that the more ancient immigration (arrived more than 10 years ago) seems to reduce pro-redistribution attitudes.

Table 9: Immigration and pro-redistribution attitudes : immigrants' origin and skills

East-Europe countries are the so-called A10 countries joining the EU after 2004 : Romania, Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, ,Slovakia, Slovenia. Low -GDP countries are countries of origin with a GDP per capita in 2000 lower than the median GDP per capita of all potential origin countries (193 countries). High -GDP countries are countries of origin with a GDP per capita higher than the median. The median has been computed in such a way that the number of immigrants in each of this two group of origin countries is equal when we sum the total of all immigrants in the 16 European destination countries

---

The sample is restricted to rightist respondent in countries in which attitudes are negatively correlated with regional immigrant stock (France, Netherlands, Norway, Sweden, Finland) *share of immigrants a decade ago (log)* is the share of immigrants in the population measured approximately 10 years before the preferences for redistribution are elicited. *inflow during the last decade* is the difference in the log of immigrants' share between  $t$  and  $t - 10$  .

## 5 Robustness (to be completed)

Table ?? tests the robustness of the finding to the use of alternative measures of attitudes towards redistribution. We have so far relied on the answers to the statement that "The government should take measures to reduce differences in income levels". In the 2008 round of the European Social Survey, a specific module has been designed to elicit attitudes towards the Welfare State. A series of different questions were asked to measure subjective opinions about taxes, social benefits, and governments' responsibility for the well-being of unemployed, old, or sick people. Interestingly, as table ?? reveals, those alternative measures are only weakly positively correlated with the main outcome variable used in the previous analysis. They generally explain less than 7% of the variability in the main outcome variable. Examining how these alternative measures are correlated with the share of immigrants therefore provides additional valuable information.

Table ?? reveals that the negative association between immigrants' share and natives' support for redistribution is robust to using these alternative measures of attitudes. This also holds when we control for the most exhaustive set of individual controls, including individual political affiliation, inequality aversion and sense of fairness (panel B).

*pro redis scale* is agreement with that Government should reduce differences in income levels. *pro-inc-equality* is the agreement with the statement that For fair society, differences in standard of living should be small. *pro-increase-taxes* is the support for Government increase in taxes and social spending. *score-pro-benefits* is the sum of disagreement with the statements that Social benefits or service cost too much in taxes or charges, that they make people lazy, that they make people less willing to care for one another, and people less willing to look after themselves/family. *progov-Healthcare* is the agreement that government should be responsible for Health care for the sick. *progov-old* is the agreement that government should be responsible for Standard of living for the old. *progov-unemployed* is the agreement that government should be responsible for the Standard of living for the unemployed. *score-progov* is sum of support for governments' responsibility for sick, old, unemployed.

## 6 Conclusions (to be completed)

European countries are receiving a larger and larger amount of immigrants not only from other European countries but also from other regions of the world. As a result their populations are becoming more heterogenous with a large increase of non natives. In this paper we show that the increase in heterogeneity of European populations is putting pressure of the generous welfare systems of these countries. Natives are becoming less favorable to redistribution presumably because they see the benefits of these policies being spread towards poorer non natives. These effects are confined to self reported right wing respondents while left leaning ones are un affected by the level of immigration: they remain favorable to redistribution even when immigration increases. We also found that the more distant (culturally) are the immigrants relative to European countries, the stronger is the anti redistribution effect on natives. While the latter seem willing to share welfare benefits with fellow Europeans they become less favorable to redistribution when the share on non European immigrants increases. These effects are much stronger for a subset of receiving countries in Northern Europe and France. We have obtained these results using a newly assembled data set on regional distribution of immigrants in 140 regions in 16 European countries, and the construction of this data set is in itself a contribution of our paper. .
