A B S T R A C T

Rare-earth doped NaYF 4 upconversion nanomaterials have found many applications from biosensing through photoelectric conversion to luminescent anti-counterfeiting. However, the scalable synthesis methods of ultra-small NaYF 4 nanoparticles are still challenging. Herein, we demonstrated that the intensified mixing of the precursor by a high-gravity rotating packed bed (RPB) reactor before the hydrothermal synthesis process enabled the preparation of ultrasmall NaYF 4 :Yb 3+ /Er 3+ upconversion nanoparticles, with much smaller size, more uniform distributions and higher Er 3+ -doping level than those obtained in the stirred tank reactor (STR) route. In stark contrast to conventional synthetic techniques that require stringent control over several experimental variables for controlling morphologies and sizes, the process intensification approach presented here requires modification of only a single variable while enabling tremendous improvements to control the formation of NaYF 4 based UCNPs with small feature size. The UCNPs dispersed well in various organic solvents (e.g. ethanol, acetone, toluene, cyclohexane, etc.), forming transparent nanodispersions with upconversion luminescence under 980 nm NIR light irradiation. The preliminary applications of NaYF 4 :Yb 3+ /Er 3+ nanodispersions for upconversion luminescent transparent hybrid films and anti-counterfeiting were also demonstrated.

1. Introduction

Rare-earth doped upconversion nanoparticles (UCNPs) that convert longer wavelength NIR light into shorter wavelength ultraviolet/visible/NIR light have attracted extensive scientific attention in recent years [1–4]. After several decades of technological developments, UCNPs have found many applications in many fields such as anti-counterfeiting [5–7], optoelectronic devices [8], bioimaging [9,10] and cancer treatment [11,12]. For instance, both theoretically and experimental studies have demonstrated that the power conversion efficiency of a solar cell would be significantly increased by using an ideal upconverter, such as transparent hybrid films embedded with UCPNs [13–15]. In addition, UCNPs have recently shown great potential to satisfy the demands for anti-counterfeiting applications due to their small size, low power density NIR excitation, high chemical stability, good wetting properties and compatibility with transparent security inks [5–7,16]. Since the traditional anti-counterfeiting technologies are easily infringed [17], an advanced anti-counterfeiting technology is therefore urgently needed in many important fields, especially for anti-counterfeiting of paper documents or certificates, such as checks, passports, and even banknotes [16,18]. The efforts of chemical engineers are to develop solutions for some important problems, including but not limited to design, operation, control, optimization, and intensification of chemical, physical, and biological processes for sustainable development [19].

Upconversion luminescence based anti-counterfeiting is one of the most promising directions in moving toward UCNPs for large-scale production and commercial applications. It has been generally accepted that ultrasmall UCNPs are beneficial for hybrid optoelectronic devices and anti-counterfeiting ink. Therefore, the development of scalable methods for the synthesis sub-10 nm UCNPs is one of key materials challenges.

UCNPs are typically composed of an inorganic host lattice and rare-earth dopant ions embedded in the host lattice [4]. Sodium yttrium fluoride (NaYF 4 ) is among the most effective host materials for upconversion luminescence process due to its lowest phonon energy (phonon cutoff ~350 cm −1 ), low nonradiative decay rates, and high radiative emission rates, especially doping with Yb 3+ /Er 3+ and Yb 3+ /Tm 3+ [3]. One common synthetic method for NaYF 4 :Yb 3+ /Er 3+ nanoparticles is based on the thermal decomposition of trifluoroacetate precursors in high boiling noncoordinating solvents [20,21]. However, the thermal decomposition approach requires expensive precursors and...
high energy consumption, which limited the scale-up production of UCNPs. Another approach for preparation of NaYF₄:Yb³⁺/Er³⁺ nanoparticles is based on liquid precipitation reaction between soluble rare-earth salts and alkali fluorides along with post hydrothermal process [22,23], which has been regarded as an effective method for mass production of UCNPs due to the low-cost and ease of scale-up. However, it is a common problem that the rare-earth doped NaYF₄ sample preparation shows two distinct particle morphologies that include small nanocubes and large nanorods, making it hard to obtain products with uniform size and well-proportioned distribution. The conventional precipitation process is usually performed in a batch-type stirred tank reactor (STR), in which the nucleation of UCNPs does not take place uniformly due to the low efficiency of mass transfer and fluid mixing in STR [24,25]. In 2010, Wang et al. reported a route for synthesis of ultra-small NaYF₄ based UCNPs with uniform morphology by doping Ga³⁺ ions, making a breakthrough in this field [26]. Simultaneous phase and size control of NaYF₄ based UCNPs through lanthanide doping lead to another issue, namely the additional of extra reactants and ions in the nanocrystal, raising the costs of raw materials and reducing the performance of the products. Herein, we propose a route for the synthesis of NaYF₄:Yb³⁺/Er³⁺ UCNPs by utilizing a high gravity rotating packed bed (RPB) reactor for nucleation of UCNPs along with post hydrothermal process. The high gravity environment and tiny droplets generated by the RPB lead to significant intensification of mass transfer and micromixing, which are of great benefit for the homogeneous nucleation and growth of particles [27,28]. Detailed studies on the effects of operating parameters and comparison with those obtained via a traditional STR route. The morphology, structure and upconversion luminescence property of the NaYF₄:Yb³⁺/Er³⁺ nanoparticles were investigated by transmission electron microscope (TEM), power X-ray diffraction (XRD), Fourier transform infrared (FTIR) spectrophotometry and luminescence spectra measurements. The upconversion luminescence behaviors of NaYF₄:Yb³⁺/Er³⁺ nanoparticles dispersed in various organic solvents were investigated. Furthermore, transparent hybrid films of NaYF₄:Yb³⁺/Er³⁺ and polyvinyl butyral (PVB), which has been among the most widely used binders for inks, were prepared by solution blending method. The NaYF₄:Yb³⁺/Er³⁺ nanoparticles were also transferred into aqueous phase and used as the ink to draw anti-counterfeiting watermarks in paper. Upconversion luminescence properties of the hybrid films and the papers under the irradiation of 980 nm NIR laser were also investigated, demonstrating the potential of the NaYF₄:Yb³⁺/Er³⁺ nanodispersions for anti-counterfeiting.

2. Experimental section

2.1. Materials

Yttrium chloride hexahydrate (YCl₃·6H₂O, 99.9%), ytterbium chloride hexahydrate (YbCl₃·6H₂O, 99.9%), erbium chloride hexahydrate (ErCl₃·6H₂O, 99.5%), were purchased from Macklin Biochemical Co., Ltd. (Shanghai, China). Oleic acid, sodium hydroxide, ammonium fluoride (NH₄F) and organic solvents were purchased from Sinopharm Chemical Reagent Co., Ltd. (Beijing, China). 1,2-distearoylsn-glycero-3-phosphoethanolamine-N-[methoxy(polyethylene glycol)-5000] (PEG) was purchased from Creative PEGWorks, Inc. The polyvinyl butyral (PVB) resin was obtained from the Sigma Aldrich. All the chemicals were used without any additional purification unless otherwise mentioned. Deionized water prepared by a Hitech Laboratory Water Purification System DW100 (Shanghai Hitech Instruments Co., Ltd.) was used for all experiments.

2.2. Synthesis of NaYF₄:Yb³⁺/Er³⁺ by STR route

For the synthesis of NaYF₄:Yb³⁺/Er³⁺ nanodispersions in a common STR reactor, 6 mL of NaOH aqueous solution (0.01 mol/mL) was mixed with 40 mL of oleic acid under vigorous stirring, forming oil-water mixture solution A. The solution B which is 22 mL of aqueous solution containing 2.56 mmol of YCl₃·6H₂O, 0.576 mmol of YbCl₃·6H₂O, and 0.064 mmol of ErCl₃·6H₂O, was added into the solution A under vigorous stirring, followed by the addition of 16 mL of solution C (i.e. aqueous solution of NH₄F with concentration of 1 mol/L). After stirring at room temperature for 15 min, the mixed solution was sealed into a Teflon-lined autoclave and heated at 200 °C for 2 h. As the solution cooled to room temperature, the paste of NaYF₄:Yb³⁺/Er³⁺ was collected by centrifugation and washing for 4 times with water and ethanol, respectively. The NaYF₄:Yb³⁺/Er³⁺ nanodispersions were then obtained by re-dispersing the paste in organic solvents (e.g. ethanol, acetone, toluene, cyclohexane, etc.) under ultrasonic treatment.

2.3. Synthesis of NaYF₄:Yb³⁺/Er³⁺ by RPB route

In order to investigate the effect of process intensification of high-gravity technology on the preparation of NaYF₄:Yb³⁺/Er³⁺ nanodispersions, a RPB reactor was used to mix the three kinds of formulated solution (solution A, B, and C) instead of mixing them in a STR. The RPB reactor consists of a rotator with stainless packing, two liquid inlets, an outlet, a casing, and a motor, and the detailed setup information on the RPB reactor can be found in our previous work [29]. The dosage and the volume of reactants were the same as those of the STR experiment. The solution A, containing 0.06 mol of NaOH, 6 mL of water, 40 mL of ethanol, and 40 mL of oleic acid, were pumped into RPB reactor through one feed inlet. The solution B (22 mL of aqueous solution containing 2.56 mmol of YCl₃·6H₂O, 0.576 mmol of YbCl₃·6H₂O, and 0.064 mmol of ErCl₃·6H₂O) and solution C (16 mL of 1 mol/L NH₄F aqueous solution) were pumped into the RPB reactor through the other feed inlet. The post hydrothermal process of the RPB route was the same as the STR experiment. In our experiment, we explored the influence of the different high-gravity level on the particle size of the UCNPs nanoparticles by changing the rotation speeds of the RPB from 1000 to 2500 rpm. As calculated by Eq. 1 [28], the high gravity levels (β) of the RPB route at various rotation speeds (1000, 1500, 2000, and 2500 rpm) were determined to be 70 g, 157 g, 279 g, and 436 g, respectively.

$$\beta = \frac{\omega^2 r}{g}$$  \hspace{1cm} (1)

where β is the high gravity level. The ω is the angular speed of the RPB reactor. The r is the geometric average radius of the rotator and g represents the gravitational acceleration speed (i.e. 9.8 m/s²).

2.4. Phase-transfer of NaYF₄:Yb³⁺/Er³⁺ nanoparticles

The phase-transfer NaYF₄:Yb³⁺/Er³⁺ nanoparticles into aqueous solution was performed by a simple phase inversion method as reported in the previous work with some modifications [30]. Briefly, 2 mL of NaYF₄:Yb³⁺/Er³⁺ nanodispersions in chloroform (10 mg/mL) and 2 mL of PEG solution in chloroform (10 mg/mL) were mixed. The mixture solution was gently heated at 50 °C in a rotary evaporator to evaporate the chloroform. Next, 5 mL of water was added to the solid mass followed by ultrasonic treatment for 5 min. The excess PEG molecules were removed by centrifugal separation and the final product of PEG coated NaYF₄:Yb³⁺/Er³⁺ nanoparticles were re-dispersed in 10 mL of water for further use.

2.5. Characterization

XRD patterns of the samples were measured by a Shimadzu XRD-6000 diffractometer. The FTIR spectra of solid samples were measured by a PerkinElmer spectrum GX Fourier system. The morphology studies of the nanoparticles were performed using a Hitachi H-9500 TEM. The
particle size distribution of the samples obtained from TEM images was measured using ImageJ. The thermogravimetric analysis (TGA) was performed using a Q50 thermogravimetric analyzer in the temperature range of 30–600°C in air atmosphere. Upconversion luminescence measurements were acquired on a PG2000 spectrometer (Ideaoptics Instruments, China) equipped with a commercial 980 nm laser. The transmissivities of NaYF₄:Yb³⁺/Er³⁺-PVB films were characterized by a Shimadzu-2600 UV-vis spectrophotometer.

3. Results and discussion

3.1. Formation of NaYF₄:Yb³⁺/Er³⁺ nanoparticles

Although the synthesis of NaYF₄:Yb³⁺/Er³⁺ UCNPs by hydrothermal route has been intensively investigated, the chemical reaction and process have rarely been put forward in previous literatures [1,26]. In Fig. 1a, the major process involved in the formation of NaYF₄:Yb³⁺/Er³⁺ nanocrystals in our route were proposed. Generally, the neutralization reaction of sodium hydroxide and oleic acid was adopted to produce free oleate ions in the oil and water mixture. The rare-earth ions (RE³⁺) then reacted with the oleate ions via complexation reaction. After the addition of fluorine ions (F⁻) in the mixture, the RE³⁺ ions released from the complex and reacted with Na⁺ and F⁻ to form NaYF₄ crystal nuclei and then grown up during the hydrothermal treatment. The following reactions occurred during the synthesis process of NaREF₄ nanoparticles.

\[
\text{C}_{17}H_{33}\text{COOH}^{-}(aq) + \text{OH}^{−}(aq) \rightarrow \text{C}_{17}H_{33}\text{COO}^{−}(aq) + \text{H}_2\text{O}(l)
\]

\[
3\text{C}_{17}H_{33}\text{COO}^{−}(aq) + \text{RE}^{3⁺}(aq) \rightarrow (\text{C}_{17}H_{33}\text{COO})_3\text{RE}(l)
\]

\[
\text{Na}^{+}(aq) + ([\text{C}_{17}H_{33}\text{COO}]_3\text{RE}(l) + \text{F}^{−}(aq) \xrightarrow{Δ} \text{NaREF}_4(s) + 3\text{C}_{17}H_{33}\text{COO}^{−}(aq)
\]

Due to the coordination of oleic acid with salts of rare-earth metal, the oleic acid adsorbed on the surface of the NaREF₄ nanocrystals and suppressed the growth of the primary particles. Since various crystal planes of NaREF₄ have different adsorption capacities of oleic acid, leading to the differences of growth speed, the uniform adsorption of oleic acid on the surface of NaREF₄ nuclei are critical for the preparation of ultrasmall nanoparticles with uniform size distribution, which requires the homogeneous micromixing of the reactants before the nucleation process. In the common route for the mixing of the precursors using a conventional STR, uniform mixing was hard to realize in all areas of the reactor in a short time (i.e. several milliseconds). Especially in the regions far from the stirring oars, if the homogeneous micromixing was not achieved after the precipitation nucleating of NaREF₄, the oleic acid molecules were not enough to cover the surface of the nuclei and the oleic acid selectively binded to some specific panels of the NaREF₄ nuclei. Therefore, large nanorods then formed due to the faster growth speed of the panels without oleic acid than those panels adsorbed oleic acid. Fig. 1b shows a typical TEM image of NaYF₄:Yb³⁺/Er³⁺ nanoparticles obtained by mixing in the conversional STR coupling with hydrothermal treatment, in which particles with two distinct morphologies including large nanorods and small nanocubes were observed and these results were consistent with the previous literature [26]. Although high-quality UCNPs have been obtained in laboratory scale by precise control of the reaction parameters such as precursor injection speed and stirring rate, it is difficult to control the uniform mixing and mass transfer upon the injection of precursor solutions in STR, which leads to low batch-to-batch reproducibility. This problem will become more prominent in the large-scale production of UCNPs (e.g., tens to hundreds of kilograms).

3.2. High-gravity-assisted synthesis of NaYF₄:Yb³⁺/Er³⁺ nanoparticles

An alternative to a batch reactor, the RPB reactor can generate a high-gravity environment with homogeneous supersaturation, concentration, and temperature, which is of benefit for the homogeneous nucleation and growth of particles. Our previous work demonstrated that the intensified mixing of RPB reactor were beneficial for the preparation of Gd₂O₃ based UCNPs [31]. By using high gravity reactive precipitation along with post calcination methods, the obtained Gd₂O₃ nanoparticles exhibited average size of ~100 nm, which is much smaller than the common route (~350 nm). Compared with the Gd₂O₃ based UCNPs reported in that work [31], the NaYF₄ based UCNPs are more...
benefit for various applications due to their higher luminescence efficiency, smaller particle size and larger dispersibility in solvents. Meanwhile, the scalable preparation of uniform NaYF₄ based UCNPs are more challenging. For instance, the requirement of homogeneous mixing at molecular level in the multicomponent and heterogeneity system (oleic acid, water, metal salts, etc.) is stronger. Based on the understanding of the process and chemical reactions involved in the formation of NaYF₄ based UCNPs as mentioned above, we propose a route for the synthesis of NaYF₄:Yb³⁺/Er³⁺ UCNPs by utilizing a RPB reactor for nucleation coupling with hydrothermal process for growth of the nanoparticles. To investigate the effect of high-gravity process intensification on the preparation of NaYF₄:Yb³⁺/Er³⁺ UCNPs, the RPB reactors operated with high-gravity levels of 157 g, 279 g and 436 g were used for the mixing of the precursors. The low magnification TEM images of the samples prepared by RPB routes with high-gravity levels of 157 g, 279 g and 436 g were shown in Fig. 2a–c, in which only small nanocubes were observed. These results demonstrated that the intensified micromixing of the precursors by the RPB reactor are beneficial for the preparation of ultrasmall NaYF₄ based nanoparticles. Due to the high-gravity field in the RPB, the liquids going through the packing were spread or split into ultrafine droplets, threads and/or thin films in the porous packing and the mass transfer and micromixing in the mixture containing oleic acid, water and metal salts, could be greatly intensified. The uniform adsorption of oleic acid molecules on the surface of NaREF₄ nuclei was achieved during the precipitation nucleating process. Therefore, the uniform surface coating of surfactants on the nuclei provided more restriction on the growth of the nanoparticles, resulting in the formation of small NaREF₄ UCNPs. It should be noted that the quality of the UCNPs exhibited in the TEM images could be further improved by purification and/or screening the samples, for example using the supernatant of the UCNPs dispersions for TEM imaging. However, in our work, we focused on the scalable synthesis of NaREF₄ based UCNPs and the effects of the intensified mixing by RPB reactors on the formation of UCNPs. The TEM images were used to reflect and express the general morphologies of the particles. These results have clearly demonstrated that there were no large nanorods obtained by using RPB route for the synthesis of UCNPs, which was promising for scalable synthesis of UCNPs with uniform size and well-proportioned distribution. The high magnification TEM images (Fig. 2d–f) and respective diameter analysis (Fig. 2g–i) indicated that the size distribution of NaYF₄:Yb³⁺/Er³⁺ UCNPs obtained by RPB routes was concentrated in the range of 10–20 nm. With increase of high-gravity level of the RPB, the mixing time of the precursor decreased, leading to shorter time for precipitation nucleating and resulting smaller nuclei. Therefore, the average size of the UCNPs obtained decreased as the increase of the high-gravity level.

3.3. Chemical structures of NaYF₄:Yb³⁺/Er³⁺ nanoparticles

The crystal structures and chemical compositions of the NaYF₄:Yb³⁺/Er³⁺ UCNPs synthesized by STR and RPB routes were then investigated by XRD, FTIR and TGA analyses. Fig. 3a shows the XRD patterns.
of the prepared NaYF4:Yb3+/Er3+ UCNPs, in which the diffraction peaks of cubic phase (JCPDS 77-2042) and hexagonal phase (JCPDS 16-0334) of NaYF4 were observed from all the four samples, with no impurity peaks. The average crystal sizes of each phase and the mass fractions from each phase in different samples were calculated according to the XRD patterns and the results were shown in Tables 1 and 2, respectively. The average crystal sizes of the samples were a little larger than the average particle size measured by TEM. The difference between the particle sizes obtained by XRD and TEM could be attributed to the fact that the XRD results reflect the crystalline particles, not the actual morphology of the particles. Besides, for the measurement of XRD large particles are usually picked, while most of the small particles are counted in TEM images. Nevertheless, the use of RBP and different high-gravity levels showed no significant influence on the average crystal size and the mass fraction from each phase of NaYF4:Yb3+/Er3+ UCNPs. It should be noted that NaYF4 contains two phases: cubic and hexagonal phase. The molar ratio of surfactants (oleic acid) and the solvents (ethanol, water) and temperature were key factors for phase control of NaYF4 nanocrystals. The XRD results demonstrated that the micromixing was not ideal homogeneous during the whole process of UCNPs synthesis and there is still room for improvement. Producing phase-pure UCNPs is important since the phase purity defines upconversion properties and should be good topics to follow.

3.4. Upconversion luminescence properties of NaYF4:Yb3+/Er3+ nanoparticles

The upconversion luminescence spectra of the four samples were presented in Fig. 4a and the data were normalized by the luminescence peak at 650 nm. All the luminescence spectra were quite similar in shape with three obvious bands in the range 520–528 nm, 539–550 nm, and 653–661 nm, which correspond to the 2H11/2 → 4I15/2, 4S3/2 → 4I15/2, and 4F9/2 → 4I15/2 transitions of Er3+ ions, respectively. Interestingly, the intensity ratio of red to green lights is increased with increasing high-gravity levels during the synthesis approaches. The possible upconversion luminescence mechanism of the investigated system was proposed in Fig. 4b. When the sample was excited by 980 nm optical fiber laser, Er3+ ions are transferred from the ground absorption peak of —C==O— in carboxyl (—COOH), and the peak at 1461 cm−1 was the characteristic absorption peak of methyl (—CH3). The TGA curves of the samples were shown in Fig. 4c, in which the weight loss below 200 °C were attributed to the loss of water absorbed on the surface of the nanoparticles. The weight reduced between 200–500 °C was caused by the desorption of O—H and the decomposition of oleic acid. The weight ratios of the organic oleic acid molecules to the inorganic NaYF4:Yb3+/Er3+ crystals for various samples were calculated according to the TGA data. A general trend was observed that the coating of oleic acid on the surface of NaYF4:Yb3+/Er3+ increased as the increasing of the high-gravity levels in the range of 157–436 g (Fig. 4d). The average size of the UCNPs obtained decreased as the increase of the high-gravity level and the surface area of the UCNPs increased, leading to the absorption of more oleic acid molecules.

state energy level \((^4I_{15/2})\) to the excited energy level \((^4I_{11/2})\) and \(\text{Yb}^{3+}\) ions on the ground state \((^2F_{7/2})\) are excited to the excited state \((^2F_{5/2})\), where the energy come from the ground state transfer (GSA) process. The \(\text{Yb}^{3+}\) will then transfer the energy to the nearby \(\text{Er}^{3+}\) ions through the energy transfer (ET) process, when the electrons of \(\text{Yb}^{3+}\) ions return to the ground state \((^2F_{7/2})\). A part of the excited electrons on the \(^4I_{11/2}\) level will populate the intermediate level \(^4I_{13/2}\) by nonradiative relaxation (NR), and other excited electrons on the \(^4I_{11/2}\) level will continue to absorb energy and populate \(^4F_{7/2}\) due to the ESA and/or ET. Then, the electrons on the intermediate level \(^4I_{13/2}\) will be excited into \(^4F_{9/2}\) by ESA and/or second-step ET, and the electrons on the excited state \(^4F_{7/2}\) will populate \(^5H_{11/2}\), \(^5S_{3/2}\), and \(^4F_{9/2}\) by NR. At last, the \(^5H_{11/2}\) level and \(^4S_{3/2}\) level undergo radiative decay to produce green emission 520–528 nm and 539–550 nm, and the \(^4F_{9/2}\) level undergoes radiative decay to produce red emission 653–661 nm. For a system with low \(\text{Er}^{3+}\) concentration, the probability of nonradiative decay from \(^4F_{7/2}\) to \(^2H_{11/2}\) or \(^4S_{3/2}\) is rather large, resulting in the dominant population at \(^2H_{11/2}\) or \(^4S_{3/2}\) level responsible for the green emission. When the concentration of \(\text{Er}^{3+}\) in nanocrystals increased, the distances between pairs of \(\text{Er}^{3+}\) ions in \(\text{NaYF}_4\) reduce correspondingly, which would lead to the near resonant cross relaxation originating from the interaction of \(\text{Er}^{3+}\) ions [32], causing the intensity quenching of green emission. Therefore, with the increase of \(\text{Er}^{3+}\) content in the medium doping range (0.2–2.0%) of \(\text{Er}^{3+}\), the green emission tends to trail off, while the red one boosts up accordingly. The spectra in Fig. 4a demonstrated that \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) particles obtained by RPB routes exhibited higher \(\text{Er}^{3+}\)-doping levels compared with those prepared by STR route, suggesting that the \(\text{Er}^{3+}\)-doping levels were enhanced with the increased high-gravity levels.

Fig. 5a shows the digital photos of the \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) nanodispersions obtained by the RPB route (high gravity level = 279 g) in various organic solvents, including ethanol, acetone, tetrahydrofuran, ethyl acetate, chloroform, toluene, and cyclohexane. The concentrations of the nanoparticles were 1 mg/ml for all the nanodispersions, which were almost transparent. Under the irradiation of 980 nm NIR light, the nanodispersions showed significant visible lines, due to the upconversion luminescence of the \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) nanoparticles (Fig. 5b). Fig. 5c presents upconversion luminescence spectrum of the nanodispersions, demonstrating that the luminescence properties of the \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) nanoparticles were stable in various organic solvents of different polarities.

3.5. \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) nanodispersion for transparent hybrid films

Polyvinyl butyral (PVB) resin has been among the most widely used binders for inks [33]. In this work, we prepared highly transparent PVB/UCNPs nanocomposites via the solvent blending method, by mixing 20 mL of \(\text{NaYF}_4: \text{Yb}^{3+}/\text{Er}^{3+}\) nanodispersions (0.5 mg/mL in chloroform) with 1 g of PVB followed by the evaporation of the chloroform. Fig. 6a shows typical pictures of a PVB film (1 cm x 1 cm x 100 μm) and a PVB/UCNPs hybrid film (1 cm x 1 cm x 100 μm). Both films were highly transparent as words under the films could be clearly observed. Fig. 6b shows the transmittance spectra of the PVB film and the PVB/UCNPs hybrid films with different mass of UCNPs:PVB (1:100, 3:100, and 5:100).

![Fig. 5.](image-url)
Fig. 6. (a) Digital photographs of a PVB film (1 cm × 1 cm × 100 μm) and a PVB/UCNPs hybrid film (1 cm × 1 cm × 100 μm) under daylight. (b) Transmittance spectra of the PVB film and the PVB/UCNPs hybrid films with different mass ratios of UCNPs:PVB (1:100, 3:100, and 5:100); (c) Typical images of PVB film and PVB/UCNPs hybrid film under the irradiation of 980 nm NIR light (2 W/cm²).

Fig. 7. (a) FTIR spectra of UCNPs, PEG and UCNPs@PEG. (b) Luminescence spectra of the aqueous nanodispersions of UCNPs@PEG under the 980 nm laser excitation. (c) Digital photos of a piece of paper with watermarks drawn with aqueous nanodispersions of NaYF₄:Yb³⁺/Er³⁺ under day light. (b–c) The upconversion luminescence imaging of the paper under irradiation of 980 nm NIR light (3.5 W/cm²). (d) Schematic diagram of the watermarks.
All the films exhibited similar transmittance behavior in the range of 200–800 nm, indicating that NaYF₄:Yb⁺³/Er³⁺ nanoparticles dispersed well in the PVB matrix with no significant aggregates. Although the two films are indistinguishable from each other in daylight, under the irradiation of 980 nm NIR light, the PVB/UCNPs hybrid film exhibited bright visible emission while no emission was observed from the pure PVB film (Fig. 6c). These results suggest the promising application of the PVB/UCNPs nanocomposites for anti-counterfeiting applications.

3.6. NaYF₄: Yb⁺³/Er³⁺ nanodispersion for anti-counterfeiting

After phase-transfer treatment of the NaYF₄:Yb⁺³/Er³⁺ nanoparticles by PEG coating, aqueous nanodispersions of UCNPs@PEG were prepared as anti-counterfeiting printing ink. Fig. 7a presents the FTIR spectra of UCNPs, PEG and UCNPs@PEG, demonstrating the successful coating of PEG on the surface of UCNPs. Fig. 7b showed the upconversion luminescence spectra of UCNPs@PEG in water, which was similar as the luminescence spectra of UCNPs powders and dispersions in organic solvents (Figs. 4a and 5c), demonstrating that the phase-transfer treatment of the NaYF₄:Yb⁺³/Er³⁺ caused no significant changes to the luminescence properties. Furthermore, we demonstrated the use of NaYF₄:Yb⁺³/Er³⁺ nanodispersions to draw watermarks by a pen on the commercially available paper. Fig. 7c shows a typical picture of the paper with “invisible” characters drawn by NaYF₄:Yb⁺³/Er³⁺ nanodispersions under daylight. However, under the irradiation of 980 nm NIR light, the forgery-proof watermark images can be identified clearly, showing the characters of UCNP and BUCT (Fig. 7d–f). According to the long-term observation for two weeks, the watermarks adhered well to the paper and exhibited significant upconversion luminescence signals with no changes. These primary results demonstrated the potential of NaYF₄:Yb⁺³/Er³⁺ nanodispersions for anti-counterfeiting in various substrates.

4. Conclusions

We demonstrate that the intensified mixing of the precursor by a high-gravity rotating packed bed reactor before the hydrothermal synthesis process enabled the preparation of ultrasmall NaYF₄:Yb⁺³/Er³⁺ nanoparticles, without the need for stringent control over several experimental variables and additional of extra reactants. According to the morphology studies, the as-prepared NaYF₄:Yb⁺³/Er³⁺ nanoparticles in RPB route exhibited much more uniform distribution and smaller size, than those obtained in the common STR route, due to the intensified mixing by the high-gravity RPB reactors. The upconversion luminescence spectra measurements indicated that Er³⁺-doping levels for anti-counterfeiting ink on the commercially available paper. Fig. 7c shows a typical picture of the paper with “invisible” characters drawn by NaYF₄:Yb⁺³/Er³⁺ nanodispersions under daylight. However, under the irradiation of 980 nm NIR light, the forgery-proof watermark images can be identified clearly, showing the characters of UCNP and BUCT (Fig. 7d–f). According to the long-term observation for two weeks, the watermarks adhered well to the paper and exhibited significant upconversion luminescence signals with no changes. These primary results demonstrated the potential of NaYF₄:Yb⁺³/Er³⁺ nanodispersions for anti-counterfeiting in various substrates.
