Thanks to Raj Chetty and Amy Finkelstein for generously providing their lecture notes, some of which are reproduced here.
Welfare Analysis of Health Insurance

- Significant evidence of adverse selection in health insurance markets

- How does this affect welfare analysis?
  - What are the optimal subsidies or mandates (if any)?

- Begin with static model of Einav, Finkelstein, and Cullen (2010)

- Extend to ex-ante welfare analysis (Hendren, 2018)

- Extend to dynamic models of insurance
1 Static Revealed Preference Welfare

2 Static Ex-Ante Welfare

3 Dynamic Insurance Model

4 Market Power and Networks
Setup

- Individuals experience utility given by
  \[ u(c, m; \theta) \]
  
  where \( c \) is consumption, \( m \) is medical expenditure, and \( \theta \) is a health shock.

- After learning \( \theta \), individuals choose \( c \) and \( m \) subject to a budget constraint.
  - Budget constraint depends on whether they are insured.
  - Insured budget constraint
    \[ c^I(\theta) + x\left(m^I(\theta); \theta\right) + p_I \leq y(\theta) \]
  - Uninsured budget constraint
    \[ c^U(\theta) + m^U(\theta) + p_U \leq y(\theta) \]

- \( p_U \) and \( p_I \) are the price of being uninsured and insured respectively.
- \( y(\theta) \) is income (which might be affected by the shock).
- \( x \) is out-of-pocket medical expenses.
Insurance Demand

- Individuals choose whether or not to purchase insurance after learning a signal, \( s \in [0, 1] \), about their risk
  - WLOG \( s \) orders demand so that \( s = 0 \) is the highest WTP type

- Demand given by \( D(s) \), which solves

\[
E\left[u\left(y(\theta) - x\left(m^I(\theta); \theta\right) - D(\tilde{s}) - p_U, m^I(\theta); \theta\right) | \tilde{s}\right] = E\left[u\left(y(\theta) - m^U(\theta) - p_U, m^U(\theta); \theta\right) | \tilde{s}\right]
\]

- Assume does not vary with \( p_U \) (only relative price matters)
  - True if CARA utility (exercise to show this!)
- Fraction of the market purchasing insurance, \( s \), solves \( D(s) = p_I - p_U \)
Following Einav, Finkelstein, and Cullen (2010), define marginal and average cost curves

- Average cost of enrollees when fraction $s$ of the market is enrolled:

$$AC(s) = E \left[ m'(\theta) - x(m'(\theta); \theta) \mid \hat{s} \leq s \right]$$

- Marginal cost of additional enrollees brought in by lowering prices. Note that total cost is $sAC(s)$, so that marginal cost is given by:

$$MC(s) = \frac{d}{ds} \left[ sAC(s) \right]$$

$$= \frac{d}{ds} \int_{\hat{s} \leq s} E \left[ m'(\theta) - x(m'(\theta); \theta) \mid \hat{s} \leq s \right] d\hat{s}$$

$$= E \left[ m'(\theta) - x(m'(\theta); \theta) \mid \hat{s} = s \right]$$

where the last line assumes $m'$ is not affected by insurance purchase

- e.g. no Becker and Ehrlich (1972) effects
Competitive Equilibrium

- Suppose there are at least two firms that compete over relative price for $H$ versus $L$ plan
  - Weyl and Viega (2016) discuss issues with multiple plan prices
- Competitive equilibrium from 2-stage game
  - Insurers post prices
  - Individuals choose insurance contracts
- Competitive equilibrium characterized by
  \[
  s^{CE} = \max \{ s \mid D(s) = AC(s) \}
  \]

  with price $p^{CE} = D(s^{CE})$
  - Why the maximum market size?
- Smetters and Scheuer (2016): minimum price not reached (ACA website?)
Competitive Equilibrium with Adverse Selection

Figure 2 (continued)

B: Adverse Selection with Complete Unraveling

Price

Quantity

AC curve

MC curve

Demand curve

Q_{\text{max}}
If prices must reflect average costs, EFC2010 and Akerlof (1970) note that this can lead to some efficient trades not taking place

- Those with \( D(s) \in (MC(s), AC(s)) \) are willing to pay their marginal cost of insurance but remain uninsured in a competitive equilibrium
- “Efficient” for all those with \( D(s) \geq MC(s) \) to purchase insurance

\[
D\left(s^{\text{eff}}\right) = MC\left(s^{\text{eff}}\right)
\]

Can quantify the size of this “deadweight loss” from foregone trades

\[
DWL = \int_{s \in [s^{CE}, s^{eff}]} \left[ D(s) - MC(s) \right] ds
\]

What is the aggregate willingness to pay above costs for trades that go unmet in a competitive equilibrium?
Competitive Equilibrium with Adverse Selection

Separating Moral Hazard from Adverse Selection

- How does the modeling approach deal with moral hazard?
  - Impact of insurance on $m$: $m^I > m^U$
- Can define cost of $s$ type as if they are insured and uninsured
- Cost relevant for the insurer is the cost they pay, $E [m^I - x (m^I) | s]$
- But, this could be higher than the costs they would pay if the individual consumed care as if she were uninsured, $E [m^U - x (m^U) | s]$
- Moral hazard of $s$ type is given by $E [m^I - x (m^I) | s] - E [m^U - x (m^U) | s]$
  - Requires identifying $E [m^U - x (m^U) | s]$
  - Tough if $x$ is nonlinear, but if linear (or full insurance) just need to identify cost curve of the uninsured, $E [m^U | s]$
Figure 5
The “Positive Correlation” Test for Selection

Competitive Equilibrium with Adverse Selection
Einav, Finkelstein, and Cullen (2010 QJE) note that one can estimate these costs using exogenous variation in prices.

- Can estimate BOTH demand and cost curve
  - Demand = fraction that buy at posted price
  - Cost = added cost on policy $H$ versus $L$ for those who purchase at posted price
  - Rarely does price variation identify both supply + demand!

- But need some institutional structure that randomly varies prices...
  - Alcoa! (they make aluminum)
  - Business unit heads choose price charged for high versus low coverage plans
Results suggest welfare loss is “small”
- $9.55/employee (~2% of the average price)

Beautiful paper - starts with theoretical graph and maps empirical objects directly onto this graph

But a few limitations:
- Paper takes contracts as given
  - Perhaps the contracts were inefficient? (Rothschild and Stiglitz 1976)
  - Multiple insurance contracts: Equilibrium existence problems (Azavedo and Gottlieb, 2016; Weyl and Viega, 2016)
  - Would competition on other dimensions unravel the market in practice?

Main question: does the welfare cost of foregone trades correspond to maximizing utilitarian welfare?
1. Static Revealed Preference Welfare

2. Static Ex-Ante Welfare

3. Dynamic Insurance Model

4. Market Power and Networks
Insurance demand depends on knowledge/beliefs of risk

Individuals often have some knowledge about risk when measuring demand, generating adverse selection

Value of foregone trades is unstable measure of welfare (Hirshleifer, 1971)

Hendren (2017): Can be misleading for optimal policy analysis
Motivating Example (Hendren, 2017)

- Begin with simple example to illustrate issue and a solution
- Individuals have $30
- Face a risk of losing $m, uniformly distributed between 0 and 10
- Willing to pay $0.50 markup for full insurance if CRRA is 3
  - Indifferent between roughly $24.50 versus uniformly distributed consumption on [20, 30]
  - Would be “efficient” for everyone to have $25 with certainty
    - Value of insurance market is $0.50
- How does this map to demand and cost curves?
Ex-Ante Demand and Cost

![Graph showing Ex-Ante Demand and Cost with horizontal lines for demand and cost at a constant value.](image)
$s^{CE} = 1$
Ex-Ante Demand and Cost

\[ W^{Ex-Ante} = 0.50 \]

\[ s^{CE} = 1 \]
Motivating Example

- What if people have information about their risk when we measure demand?

- Begin with extreme case: suppose individuals learn their loss
  
  - Willingness to pay equals cost, $D(s)=m(s)$
Observe Demand and Cost

Fraction Insured ($s$) vs. Observed Demand and Marginal Cost

- **Observed Demand** (solid line)
- **Marginal Cost** (dashed line)
Observe Demand and Cost

![Graph showing observed demand, marginal cost, and average cost as functions of the fraction insured (s). The graph shows three lines: a solid black line for observed demand, a dashed red line for marginal cost, and a dashed blue line for average cost. The x-axis represents the fraction insured (s), ranging from 0 to 1, and the y-axis represents the observed demand, marginal cost, and average cost, ranging from 10 to 0.]
Observe Demand and Cost

\[ s^{CE} = 0 \]
Observe Demand and Cost

What are the welfare implications of this unraveling?

\[ s^{CE} = 0 \]
Observe Demand and Cost

\[ DWL = 0 \]

No lost surplus from foregone trades

\[ s^{CE} = 0 \]

Market Surplus is Unstable Measure of Welfare

\[ WTP_{Ex-Ante} \geq E[WTP_1] \geq E[WTP_2] \geq E[WTP_3] = \text{Cost} \]
**Problem:** Revealed preference does not deliver a stable welfare metric corresponding to expected utility

- Depends on amount of information that happens to be revealed when insurance choices are made
- Same insurance policies (e.g. value of a mandate) may have different welfare properties simply because of when the econometrician chooses to measure WTP!
Goal of Paper: Evaluate policies in markets where information has been revealed when measuring WTP (i.e. adverse selection)

- Use stable welfare criteria corresponding to ex-ante expected utility
  - Condition on observables (e.g. income) to isolate redistribution

Observed WTP
Motivating Example

- Observed demand does not capture the value of insurance against learning about your risk prior to demand measurement
  - Adverse selection implies a divergence between DWL and Ex-Ante Welfare
Motivating Example

- Observed demand does not capture the value of insurance against learning about your risk prior to demand measurement
  - Adverse selection implies a divergence between DWL and Ex-Ante Welfare

- Hendren (2017) derives an “ex-ante” demand curve to facilitate welfare analysis from behind the veil of ignorance
  - Combine Einav, Finkelstein, and Cullen (2010) with Baily-Chetty
Deriving the Ex-Ante Demand Curve

- Return to example in which \( D(s) = m(s) \)

- Suppose \( s = 50\% \) of the population has insurance

- Obtained by setting prices subject to a resource constraint:
  - Price of insurance, \( p_I \)
  - Price/penalty of being uninsured, \( p_U \)
  - Set so that \( sp_I + (1-s)p_U = sAC(s) \)
From Observed Demand to Ex-Ante Demand

\[ p_I - p_U = \$5 \]

- **Fraction Insured ($s$)**
- **Demand**
- **Marginal Cost**
- **'Ex-ante' Demand, $D(s)+EA(s)$**

The graph shows the relationship between the fraction insured ($s$) and the demand, marginal cost, and 'ex-ante' demand. The 'ex-ante' demand curve is marked by a red line, and the demand and marginal cost lines are marked by black and dashed black lines, respectively.
From Observed Demand to Ex-Ante Demand

EA(0.3) =$0.88
From Observed Demand to Ex-Ante Demand

\[ EA(0.7) = \$0.38 \]
\[ \int_{0}^{1} EA(s) \, ds = $0.50 \]
From Observed Demand to Ex-Ante Demand

\[ \int_0^1 EA(s) \, ds = 0.50 = W^{Ex-Ante} \]
DWL versus Ex-Ante WTP

- Ex-ante demand curve facilitates ex-ante/utilitarian welfare analysis
  - Even though demand is measured after information is revealed

- Ex-ante (ex-post utilitarian) surplus can lead to different conclusions about the value of insurance
  - Ex-ante efficient to have full insurance
  - No value to insurance market after info is revealed
    - (Strictly positive DWL if there was moral hazard)
General Model with Moral Hazard

- Ex-ante/Utilitarian welfare when fraction s has insurance

\[ W(s) = E\left[u(c(s;\theta), m(s;\theta); \theta)\right] \]

- Ex-ante WTP for larger insurance market:

\[ \frac{W'(s)}{E[u'|\text{Insured}]} = \frac{D(s) - MC(s) + EA(s)}{\text{Ex-Post Surplus}} \]

where

\[ EA(s) = (1 - s) \left( MDWL(s) - s \frac{\partial D}{\partial s} \right) \frac{E[u'(s)|\text{Insured}] - E[u'(s)|\text{Uninsured}]}{E[u'(s)|\text{Insured}]} \]

- Adjust size of transfer for MDWL=MC(s)-D(s)
Implementation

- Use common assumptions to approximate difference in marginal utilities between insured and uninsured
  - State independence: $u_c$ only depends on $c$
  - Income doesn’t vary with $s$
  - Common risk aversion (Andrews and Miller, 2013)

- Implies:

\[
EA(s) = (1 - s) \left( \text{MDWL}(s) - s \frac{\partial D}{\partial s} \right) \left( \frac{-u_{cc}}{u_c} \right) E \left[ D(s) - D(s') | s' > s \right]
\]

- Ex-ante component increasing with the square of demand/cost
  - $D(s) \rightarrow aD(s)$ implies $EA(s) \rightarrow a^2EA(s)$
Risk Aversion

- Measuring ex-ante demand requires risk aversion
- Can be assumed externally
  - CRRA = 3
  - CARA = 5x10^{-4}
- Or can be estimated internally

\[
\frac{-u_{cc}}{u_c} \approx 2 \frac{\text{Markup}}{\text{Variance Reduction}} \approx 2 \frac{D(s) - MC(s)}{\text{var}(m^U) - \text{var}(x^I)}
\]

- WTP for insurance against remaining risk reveals can proxy for WTP for insurance against realized risk
Illustration to Einav, Finkelstein, and Cullen (2010)

1. Top-up market for more generous PPO coverage in Alcoa

Ex-Ante Optimal Insurance Markets Generate DWL

- Ex-ante optimal size of the insurance market solves:
  \[
  \frac{W'(s^{Ex-Ante})}{E[u'|Insured]} = D(s^{Ex-Ante}) - MC(s^{Ex-Ante}) + EA(s^{Ex-Ante}) = 0
  \]

- Yields a “Baily-Chetty” condition:
  \[
  EA(s^{Ex-Ante}) = MDWL(s^{Ex-Ante})
  \]

- **Corollary:** The ex-ante optimal allocation generally involves (ex-post) deadweight loss
  - Easy to show that MDWL(s)=0 implies EA(s)>0 whenever marginal utilities are higher for the insured than uninsured
  - MDWL is a cost we’re willing to accept for ex-ante insurance
Top-Up Health Insurance (EFC2010)

Medium Risk (4x EFC2010)

DWL captures 32% of ex-ante welfare cost of adverse selection

\[ W^{\text{Ex-Ante}} = $120.62 \]

\[ \text{DWL} = $38.26 \]
Large Risk (8x EFC2010)

DWL captures 18% of ex-ante welfare cost of adverse selection.

$W^{Ex-Ante} = \$427$

$DWL = \$77$

DWL captures 18% of ex-ante welfare cost of adverse selection.
Ex-ante Insurance Value Increasing in Premium

- Divergence between Observed and Ex-ante value of insurance is increasing in the size/importance of the risk
  - DWL captures 67% of the ex-ante welfare cost of adverse selection for baseline specification in Einav, Finkelstein, and Cullen (2010)
  - Only 18% if risks are 8x as large

- More important for risks where the premiums are a significant share of people’s incomes
  - Health, life, disability, unemployment insurance
  - Less important for iPhone insurance...
Competitive Markets vs. Mandates

- Are competitive markets better or worse than govt mandates?
  - Competitive markets suffer adverse selection
  - Mandates may require some to buy insurance that don’t want it
Markets vs. Mandates: Medium Risk (4x EFC2010)

- Ex-Post
- DWL = $38.26
- DWL = $117.84

Fraction Insured

Demand
Marginal Cost

Markets vs. Mandates: Medium Risk (4x EFC2010)

'Ex-ante' Demand
Markets vs. Mandates: Medium Risk (4x EFC2010)

Ex-Ante Welfare prefers mandate

\[ W_{\text{Ex-Ante}}^{\text{Ex-Ante}} = $120.62 \]

\[ W_{\text{Ex-Ante}}^{\text{Ex-Ante}} = $94.7 \]
For the medium and large risk specifications, ex-ante and ex-post (DWL) welfare measures generate different conclusions.

- DWL perspective prefers markets
- Ex-ante/utilitarian perspective prefers mandates
Key Lessons

- Insurance insures against the realization of risk
  - Adverse selection implies a divergence between DWL and Ex-ante welfare

- Exploit Baily-Chetty logic to create ex-ante demand curve
  - Conduct utilitarian/ex-ante welfare analysis

- DWL and Ex-ante welfare can differ in conclusions about:
  - Optimal size of insurance market
  - Welfare cost of adverse selection
  - Competitive markets vs. mandates
  - Difference between DWL and Ex-ante welfare increasing in size of risk
1. Static Revealed Preference Welfare

2. Static Ex-Ante Welfare

3. Dynamic Insurance Model

4. Market Power and Networks
Reclassification Risk

- Suppose there are $T$ periods
  - No discounting for simplicity
- Each period, medical spending shock $m_t$ is realized
  - Shocks can be persistent: future $m_{t+1}$ correlated with $m_t$
  - No choice in $m_t$ (can be extended)
- Ex-Ante (time 0) budget constraint

\[
E \left[ \sum_t c_t \right] = E \left[ \sum_t y \right] - E \left[ \sum_t m_t \right]
\]

- Equivalent to selling claims to $y_t$ and buying insurance in competitive ex-ante market to cover cost, $m_t$ (price in the market equals probability)
- Utility given by

\[
E \left[ \sum_t u(c_t) \right]
\]
Ex-ante optimal allocation, \( \{c_t\} \), solves

\[
u'(c_t) = \lambda \quad \forall t
\]

where \( \lambda \) is the lagrange multiplier on the budget constraint

- Individuals are fully insured
  - State independent utility implies \( c_t = \bar{c} = E[\sum_t y] - E[\sum_t m_t] \)
Implementing the Optimal Allocation

- Are ex-ante contingent claims time-consistent?
  - No. Suppose you get a positive health shock – might want to withdraw and consume future endowment
    - Requires commitment to sell future income stream to cover health costs
    - But healthy people might want to leave!

- Cochrane (1996): Can implement with 1-period contracts

- Each period $t$ buy insurance that pays $t_t (m_{t+1})$ if $m_{t+1}$ occurs in period $t + 1$ at price $q_t (m_{t+1}|m_t) = \Pr \{ m_{t+1}|m_t \}$

$$c_t (m_t) + m_t + \sum_{m_{t+1}|m_t} t_t (m_{t+1}) q_t (m_{t+1}|m_t) = y + t_{t-1} (m_t)$$

- Lagrange multiplier $\lambda_t (m_t) = \text{marginal utility of consumption if } m_t \text{ is realized}$
Time Consistent Allocation

- Consider period $t$ optimization after $m_t$ has been realized

- Can collapse period $t' > t$ budget constraints (recursively substitute out $t_t (m_{t+1})$)

\[
c_t + m_t = y - E \left[ \sum_{t' > t} m_{t'} | m_t \right]
\]

or

\[
c_t = y - E \left[ \sum_{t' \geq t} m_{t'} | m_t \right]
\]
The maximization becomes

$$\max E \left[ \sum_{t' \geq t} u(c_t) \mid m_t \right]$$

subject to

$$c_t = y - E \left[ \sum_{t' \geq t} m_{t'} \mid m_t \right]$$

Claim: can equate marginal utilities across all states/time periods:

$$u'(c_{t'}) = \lambda(m_t)$$

for all $t' \geq t$

WLOG, extend back to $t = 0$ and we can implement the first best!
What do the insurance products look like that implement the first best?

Each period:

\[
\tilde{c} + m_t + \sum_{m_{t+1}} t_t (m_{t+1}) q_t (m_{t+1} \mid m_t) = y + t_{t-1} (m_t)
\]

or

\[
\tilde{c} + m_t + E [t_t (m_{t+1}) \mid m_t] = y + t_{t-1} (m_t)
\]

or

\[
t_{t-1} (m_t) = \underbrace{m_t + \tilde{c} - y + E [t_t (m_{t+1}) \mid m_t]}_{\text{Net Deficit}} + \underbrace{E [t_t (m_{t+1}) \mid m_t]}_{\text{Future Insurance Cost}}
\]

Payments, \( t_{t-1} (m_t) \), are increasing in \( m_t \) for **two** reasons:

- Medical shock, \( m_t \)
- Impact of \( m_t \) on future insurance costs, \( E [t_t (m_{t+1}) \mid m_t] \)
- "Reclassification Risk"
But, we don’t see markets for “reclassification risk” insurance
   Why?

Private information about future realizations of $m_t$
   Akerlof unraveling?
   No evidence of this, but could be true...

Lack of 1-period commitment (Hendel and Lizzeri, 2003)
   Good realizations of $m_t$ may induce people to “run” from the contract
     Can implement with zero profits in each period, but requires $t_t (m_{t+1}) < 0$ for some realizations of $m_{t+1}$
     Incentive to leave the contract and not pay!
Solution: Front-load the contract!
- Pay the insurer lump sum upfront
- Can sustain $t_t (m_{t+1}) \geq 0$ in all future periods so that consumers never wish to leave the contract
- Hendel and Lizzeri (2003) argue this explains why life insurance contracts are front-loaded

Many reasons to want to front-load insurance contracts
- Prevents ex-post healthy people from leaving the risk pool

But, if front-loading helps increase commitment, should people be allowed to re-sell their insurance contracts?
- “Life settlement” market (Fang and Kung, 2010)
WHAT IS A LIFE SETTLEMENT?

A life settlement is a cash settlement obtained through the sale of your existing life insurance policy.

When life insurance is no longer wanted or needed a life settlement can be a much more valuable financial option than surrendering or lapsing your insurance. The beauty of a life settlement is that you receive a cash settlement that is significantly more than what your insurance company will pay and you will be free from the obligation and financial burden of paying future premium payments.

GET A FREE, NON-BINDING APPRAISAL
Should people be allowed to re-sell their insurance contracts?

- “Life settlement” market

Downside: Prevents commitment

Upside: Increases flexibility / choice

- But choice not necessarily welfare improving with asymmetric information

In general, if first period insurance contracts were optimal but required commitment, then re-trading in life settlement markets ex-post will reduce welfare
In practice, most health insurance contracts do not look like optimal contracts in Cochrane (1996)
  - Repeated static contracts
  - Perhaps because of both commitment and private information problems?

Opens up important questions in optimal insurance designs
  - Community rating versus adverse selection

Simulate model of health insurance with repeated static insurance contracts

- Community rating: everyone pays same price
- Risk-based pricing: prices of insurance is risk-rated

Community rating generates adverse selection within periods

- Healthy people don’t buy insurance
  - Wait until they’re sick to buy
- Leads prices for insurance to be too high

Risk-based pricing generates risk against the realization of health conditions

- Expose to reclassification risk: higher price of insurance if sick

Results: community rating generates significant adverse selection but 5x higher welfare than risk-based pricing

- Reduces reclassification risk!
Simulate model of health insurance with repeated static insurance contracts

  - Community rating: everyone pays same price
  - Risk-based pricing: prices of insurance is risk-rated

Community rating generates adverse selection within periods

  - Healthy people don’t buy insurance
    - Wait until they’re sick to buy
  - Leads prices for insurance to be too high

Risk-based pricing generates risk against the realization of health conditions

  - Expose to reclassification risk: higher price of insurance if sick

Results: community rating generates significant adverse selection but 5x higher welfare than risk-based pricing

  - Reduces reclassification risk!

Studies Medigap Market
- Medicare pays 80% of bills; coinsurance of 20%
- Medigap reduces this 20% (several standardized/regulated policies available)

Two regulatory regimes that vary by states:
- Community rating for all ages
- Open enrollment period (6-months) at age 65
  - Followed by ability of insurers to underwrite post age 65
  - But, if purchased at age 65, policy is guaranteed renewable
Incentives under community rating?
  - Wait until sick to buy Medigap...

Curto (2016) provides evidence for this strategic behavior

Empirical strategies:
  - Compare take-up across states with different policies
  - Robustness: explore differences only along border discontinuities
Figure 4: Age at First Purchase among Medigap Buyers

- Community Rating (CR)
- Guaranteed Renewal (GR)
- Community Rating with Rejections (CRR)

Notes: This figure shows a histogram of age at first Medigap purchase among Medigap buyers. The sample is restricted to individuals living in Community. 

Nathaniel Hendren (Harvard and NBER)
Figure 12: Medigap Enrollment during Onset of Chronic Health Condition

Notes: This figure shows estimates of Medigap enrollment for each of the years prior to and after the onset of a chronic health condition. The chronic health conditions examined are severe cancers including those of the lung and upper digestive tract. The sample is all aged Medicare beneficiaries ever diagnosed with this health condition between 2006 and 2010. Year 0 is defined as the first year the health condition was diagnosed. Estimated coefficients are obtained from a regression of Medigap coverage on yearly indicators and individual fixed effects. The bars show 95 percent confidence intervals.
1. Static Revealed Preference Welfare
2. Static Ex-Ante Welfare
3. Dynamic Insurance Model
4. Market Power and Networks
Considerable evidence of lack of competition in several dimensions:
- Health insurers
- Health providers

Additional reason for insurance: bargaining power with providers

Generates role of provider networks
- Ability to go to some but not all hospitals
Shepard (2016), “Hospital Network Competition and Adverse Selection: Evidence from the Massachusetts Health Insurance Exchange”

- Star hospitals (e.g. MGH) attract sicker patients (adverse selection) and also cause an increases in costs (moral hazard)

- But, people have strong demand for them!
  - Adverse selection can lead to inefficiently low coverage of star hospitals
  - But, adverse selection can reduce market power effects
    - higher prices $\rightarrow$ higher costs $\rightarrow$ less incentive to raise prices and exploit market power

- [Aside: Thanks to Mark Shepard for sharing his presentation slides!]
## High-Price Star Hospitals: Partners Healthcare

Evidence from Network Changes

- **Additional evidence**: How do selection patterns, costs respond to change in network coverage of Partners?

- **Biggest change**: Large plan (Network Health) drops Partners (+ several other hospitals) in 2012

- How did network changes affect selection and costs?
  - **Selection**: Look at plan switching
  - **Cost changes (moral hazard)**: Analyze cost changes for non-switchers
Shepard (2016): Main Results

- Costs to policy decrease after Network Health plan drops Partners
- Is this moral hazard or adverse selection?
  - Study costs on those who don’t switch policies
  - Finds some reduction in costs
  - Indicates “moral hazard”
Evidence of Overall Cost Reductions for Stayers

Note: Points are group x time coeffs. from regression with individual fixed effects.
Shepard (2016): Main Results

- Paper sets up structural model to:
  - Study the welfare impact of covering a star hospital?
    - e.g. do too few or too many plans include MGH?
  - Studies counterfactual policies (e.g. increased risk adjustment)
    - Can prevent unraveling of coverage of star hospitals
    - But this doesn't increase welfare on net

- Main Lessons:
  - Adverse selection discourages covering star hospitals
    - Adverse selection may help explain rise in narrow network plans
  - Additional non-risk channel for thinking about adverse selection: selection on use of higher-cost option
    - Do people value this from an ex-ante perspective?
Einav, Finkelstein and Cullen (2010) provide baseline framework for welfare analysis of insurance

But, may not capture ex-ante welfare because information is realized over time (Hendren, 2017)

Suggests may be willing to trade off adverse selection for insurance against reclassification risk (Handel, Hendel, and Whinston, 2015)

But first-best would be to have dynamic re-classification contracts that insure against higher premiums in the future (Cochrane, 1996)

Alternatively, can front-load insurance contracts and have dynamic commitment (Hendel and Lizzeri, 2003; Curto, 2016)

- e.g. Life insurance, LTC insurance, disability insurance, health?

Health insurance also provides access to providers

- Additional adverse selection on preference for hospitals
- Creates more complicated welfare/design questions
