Planning prompts as a means of increasing preventive screening rates

Keywords: Reminder systems, Communication, Economics, Behavioral, Primary prevention, Colonoscopy, Memory

In the U.S., 18,800 lives could be saved annually if those advised to obtain colorectal screenings based on national guidelines complied (Zauberman et al., 2012). Subtle suggestions embedded in a decision-making environment can change people’s choices (Thaler and Sunstein, 2008). Past research has shown that prompting people to form plans about where and when they will complete an intended behavior increases engagement in activities ranging from voting to vaccination (Gollwitzer and Sheeran, 2006; Milkman et al., 2011; Nickerson and Rogers, 2010). When plans are formed, they link intended behaviors with a concrete future moment and course of action, creating cues that reduce forgetfulness and procrastination. We studied whether planning prompts increase colonoscopy rates.

In summer 2010, 11,918 employees from four U.S. companies were selected for the study because they were due for a colonoscopy according to the Centers for Disease Control criteria (USPSTF, 2008). Evive Health, a healthcare communications provider, randomly assigned these employees to a control or planning group and sent each a mailing explaining that national guidelines recommended they receive a colonoscopy. Mailings provided contact information for a proctologist, listed the percentage of cost covered by insurance, and emphasized that sticky notes help people remember to accomplish important tasks (like getting a colonoscopy). A blank yellow sticky note was attached to the top of the control group mailing. For the planning group, the mailing was identical, except the sticky note was attached to the top of the control group mailing. We analyzed colonoscopy medical claims of study participants from the time of the mailings through February 2011. The 7.2% colonoscopy rate of the planning group was significantly higher than the 6.2% rate of the control group (Table 1), a relative increase of 15%.

Our results show that planning prompts, at no additional cost and without restricting choice, can increase follow-through on unpleasant and temporally distant health behaviors like colonoscopies.

Letter to the Editor

Planning prompts as a means of increasing preventive screening rates

In the U.S., 18,800 lives could be saved annually if those advised to obtain colorectal screenings based on national guidelines complied (Zauberman et al., 2012). Subtle suggestions embedded in a decision-making environment can change people’s choices (Thaler and Sunstein, 2008). Past research has shown that prompting people to form plans about where and when they will complete an intended behavior increases engagement in activities ranging from voting to vaccination (Gollwitzer and Sheeran, 2006; Milkman et al., 2011; Nickerson and Rogers, 2010). When plans are formed, they link intended behaviors with a concrete future moment and course of action, creating cues that reduce forgetfulness and procrastination. We studied whether planning prompts increase colonoscopy rates.

In summer 2010, 11,918 employees from four U.S. companies were selected for the study because they were due for a colonoscopy according to the Centers for Disease Control criteria (USPSTF, 2008). Evive Health, a healthcare communications provider, randomly assigned these employees to a control or planning group and sent each a mailing explaining that national guidelines recommended they receive a colonoscopy. Mailings provided contact information for a proctologist, listed the percentage of cost covered by insurance, and emphasized that sticky notes help people remember to accomplish important tasks (like getting a colonoscopy). A blank yellow sticky note was attached to the top of the control group mailing. For the planning group, the mailing was identical, except the sticky note was attached to the top of the control group mailing. We analyzed colonoscopy medical claims of study participants from the time of the mailings through February 2011. The 7.2% colonoscopy rate of the planning group was significantly higher than the 6.2% rate of the control group (Table 1), a relative increase of 15%.

Our results show that planning prompts, at no additional cost and without restricting choice, can increase follow-through on unpleasant and temporally distant health behaviors like colonoscopies.

A forgetfulness proxy, constructed by summing indicators for these five variables (calculated for age and coverage by dividing by their respective ranges), has a significant positive interaction with the treatment effect on colonoscopy receipt (p < 0.05).

Our results show that planning prompts, at no additional cost and without restricting choice, can increase follow-through on unpleasant and temporally distant health behaviors like colonoscopies.
