Choosing Electoral Rules: Theory and Evidence from US Cities.

Francesco Trebbi^{*}, Philippe Aghion[†], Alberto Alesina[‡]

November 2005

Abstract

This paper studies the choice of electoral rules, in particular the question of minority representation. Majorities tend to disenfranchise minorities through strategic manipulation of electoral rules. With the aim of explaining changes in electoral rules adopted by US cities (particularly in the South), we show why majorities tend to adopt "winner-take-all" city-wide rules (at-large elections) in response to an increase in the size of the minority when the minority they are facing is relatively small. In this case, for the majority it is more effective to leverage on its sheer size instead of risking to concede representation to voters from minority-elected districts. However, as the minority becomes larger (closer to a fifty-fifty split), the possibility of losing the whole city induces the majority to prefer minority votes to be confined in minority-packed districts. Single-member district rules serve this purpose. We show empirical results consistent with these implications of the model in a novel data set covering US cities and towns from 1930 to 2000.

We thank Matilde Bombardini, Gary Chamberlain, John Friedman, Edward Glaeser, Richard Holden, Caroline Hoxby, David Lucca, James Robinson, and John Wallis for useful comments and suggestions. We are grateful to participants of the CIAR meetings in Toronto and seminars at Harvard University. Dilyan Donchev, Laura Serban, and Radu Tatucu provided excellent research assistance. Trebbi acknowledges financial support from the Social Sciences Research Council.

1 Introduction

One of the key questions in political economy is how different electoral laws affect policy outcomes. In order to provide an answer several authors take electoral rules as exogenous or predetermined and use them as explanatory variables for various policies¹. However, the rules of government are themselves endogenous variables chosen at constitutional tables. Ideally, rules should be chosen behind a "veil of ignorance", that is decisions should be taken as if one ignored the identity of those benefiting from the choices themselves. In reality, however, in most constitutional tables the veil of ignorance is "see-through", in the sense that there is some knowledge of who would benefit under alternative rules and of what policy outcomes those rules would produce. Therefore the "exogeneity" of constitutions can be called into question.

Our focus is on the question of minority representation, with special reference to the nature of electoral districts and alternative rules for the choice of representatives. We have two goals in mind, one more general and one more specific. The first and more general point is to make progress in modeling institutional choice as endogenous. On the first point, most of the literature is normative, i.e. it discusses how electoral laws should be chosen, starting from the work of Hayek (1960) and Buchanan and Tullock (1962)². A normative approach usually characterizes works in Political Science, with some notable exception such as Riker (1986) and several essays in Colomer (2004). Economists have only recently begun to pay attention to the endogeneity of political institutions from a positive, as opposed to a normative perspective. Alesina and Glaeser (2004) for instance discuss how the choice of alternative electoral rules, which are themselves associated with different policy choices over the welfare state, are indeed the result of strategic constitutional choices. The present paper is a study in "positive constitutional theory", with a special emphasis on the question of how majorities select electoral rules to partially disenfranchise minorities.

The second and more specific goal of our paper is to analyze the evolution of minority representation in American cities. We examine empirical evidence drawn from US municipalities, that adopt two types of electoral rules: either a single-member district (also called single-district) or

¹A classic study is Lijphart (1994). The most recent contributions on the effects of institutions (taken as exogenous or predermined) on economic policies are Persson and Tabellini (2003) for a sample of democratic countries and Baqir (2003) for a cross-section of US cities. They build upon a vast literature on the effects of alternative forms of government on policies, a literature that we do not review here. We refer the reader to Persson and Tabellini (2003) for a survey of the cross-country literature. On US states see in particular Alt and Lowry (1994), Poterba (1994), and Bohn and Inman (1996) amongst others. Mulligan and Sala I Martin (2004) offer a dissenting view, namely that policies are determined by lobbying pressure that are not much affected by institutional forms of government.

²For a survey of the literature on Constitutional Theory, see Voigt (1997).

at-large rules (or a combination of the two). Councilmen elected by district compete for one or, more rarely, multiple seats in each geographic subdivision (district or ward) of the city. Differently, in at-large elections, officials are elected in multi-member plurality districts, voters have as many votes as there are council seats, and the only multi-member district is identified by the city itself. The basic "winner-take-all" logic holds for both rules. For given council size, the difference between single-district and at-large rules is due to geographic clustering of groups of voters with homogeneous preferences³. We show why majorities at the constitutional design stage tend to adopt at-large electoral rules in response to an increase in the size of the minority when the minority they are facing is relatively small. In this case, as the size of the minority increases, for the majority it becomes more effective to leverage on its sheer size instead of risking to concede representation to voters from minority-elected districts. However, as the minority becomes larger (closer to a fifty-fifty split), the possibility of losing the whole city induces the majority to prefer minority votes to be confined in minority-packed districts. Single-member district electoral rules serve this purpose. This shift in the preferences of the (constitutional) majority, first towards an at-large electoral rule, and then towards a single-district rule as the size of the minority increases, is precisely what the data show.

When discussing local politics in the US, one is immediately thrown into the area of race relations.⁴ In fact, it is quite compelling to identify the "majority" with the whites and the "minority" with racial "minorities". The evolution of voting rights, especially in the South, allows us to test implications of the model regarding the endogenous institutional choice. Until the midsixties, before the civil right movement and the Voting Rights Act of 1965, racial minorities (mainly blacks) in the South were essentially disenfranchised by a battery of regulations that, although colorblind on paper, were in practice directed to severely limit black vote. In this context the choice of electoral rules and forms of governments had not much to do with a white majorities' attempt at controlling black influence on city governments, since blacks did not vote. After the mid-sixties, due to novel federal Voting Rights legislation, black influence increased substantially in terms of their ability to elect representatives. Indeed, after the Voting Rights Act of 1965, we show that decisions about electoral rules reflected changes in the relative size of the white and black populations in a

³See Cutler, Glaeser, and Vigdor (1999) for a detailed account of racial segregation patterns in the United States. The assumption of geographic clustering will be maintained throughout the paper.

⁴For discussion of the importance of race in American local politics, see for instance Hacker (1992), Huckfeld and Kohfeld (1989) and Wilson (1996) amongst many others. Alesina, Baqir, and Hoxby (2004) argue that even the design and number of local jurisdictions in the US depends upon race relations. City elections are for the greatest majority explicitly nonpartisan, therefore we will leave out partisan considerations in the following discussion.

way consistent with our model.

Manipulation of electoral rules is not a prerogative exclusive of American cities. Alexander (2005, p.211) describes in detail the 1947 Gaullist manipulations of electoral rules in France. In the Paris area where the Gaullist alliance was weak they introduced proportional representation, in rural areas where the alliance was strong, they introduced plurality rule. Krenzer (2005, p.229) describes strategic manipulation in Germany. One could go on.

Our empirical results on (within-)US cities variation are quite consistent with previous findings on the cross-country evidence in Alesina, Aghion, and Trebbi (2004). In both cases constitutional choices do not seem to occur behind a veil of ignorance in the sense that, as the minority increases its size and/or its political rights, the majority tries to make constitutional changes that limit the protection of minorities, while behind a veil of ignorance exactly the opposite should happen (as one would take into account the likelihood of belonging to a minority). Finally, the construction of an extensive novel data set of US municipalities' political institutions allows for a richer set of empirical exercises, improving upon current standards in empirical political economy.

The paper is organized as follows. Section 2 develops a simple formal setup. Section 3 describes the institutional context of US city governments and introduces our data. Section 4 presents our empirical results. The last section concludes.

2 A model of the choice of electoral rules

This section presents the simplest formalization for developing our intuition and guiding our empirical analysis. The structure of the model is as follows. There are two groups of voters, whites (W) and blacks (B). We denote the initial relative size of group B as $\pi > 0$, so that the size of group W is $(1 - \pi)$. The whites are, initially at least, a majority (we restrict $\pi < 1/2$) and they are those who choose the electoral rule for the city (in short, we call the choice of the electoral rule the "constitution"). This is because either the blacks are disenfranchised at the time of the constitutional choice or they are outvoted at the constitutional table. White voters choose a constitution with an eye on maximizing their expected utility arising from a policy outcome which will be decided by an elected council. In order to make the problem interesting there is uncertainty in the relative share of the W and B voters, so that the constitutional writers cannot be sure ex ante of the composition of the council. In other words, there is a shock to the composition of the electorate between the writing of the constitution and the choice of the policy. Moreover, the composition of the council depends on the electoral rule chosen. This modeling strategy builds upon the incomplete social contracts ideas of Aghion and Bolton (2003). We now present the model more formally.

2.1 Agents and expected utility

We first present a basic version of the model. We discuss generalizations later. The population is equally spread over three electoral districts, numbered 1, 2, 3, and with M individuals in each. Each district chooses a seat in the council. The initial number of B and W voters in each district are given by B_i and W_i for i = 1, 2, 3. We assume that:

$$W_1 = M,$$

$$W_2 = W_3 = \left(\frac{1}{2} + z\right)M,$$

where z is a real number between -1/4 and 1/2. In other words, the parameter z will allow us to make comparative statics on the initial number of B voters in districts 2 and 3. Note that this range of variation for z insures that $0 < \pi < 1/2$. Thus, z parameterizes the size of the ex ante W majority. Indeed, we have:

$$\sum_{i} W_{i} = (2 + 2z)M = 3(1 - \pi)M,$$

therefore:

$$z = \frac{1 - 3\pi}{2}.\tag{1}$$

Thus, initially the W voters have a majority and they can choose the electoral rule (constitution). Given the electoral rule, a three-member council is elected. The council decides the policy. After the constitution is chosen, there is a shock to the composition of voters in the city, to which the electoral rule cannot be made contingent upon.

More formally, we suppose that during the interim phase an exogenously given mass L_N of new B voters joins the polity⁵, with $L_N = \alpha M$ where α is a random variable uniformly distributed between 0 and an upper bound $\overline{\alpha} \in (1,2)$. Moreover, we assume that the newcomers are not evenly distributed across the three districts, but that instead one half of them joins district 2, whereas the remaining half goes to district 3 (thus, no new B voter enters district 1).

Different compositions of the council imply different policies. We assume that with no W representative and three B representatives the implemented policy is most unfavorable to the W group which obtains a low utility level \underline{r} . With one W representative the W group ends up with the status quo utility level u_0 ; with two or three representatives the W group achieves its

⁵One could assume that mobility across cities is affected by the nature of charter rules, electoral systems, and the identity of the mayor, an issue which we do not tackle in the model. See Epple and Romer (1991) for a classic treatment of endogenous mobility in a political economy model. However, empirical evidence of Tiebout sorting is scant. See Strumpf and Oberholzer-Gee (2002). We discuss this effect in Section 4.

maximum utility level \overline{r} . (Think of \underline{r} as being the result of the B group's most favorable policy being implemented, and of \overline{r} as being the outcome of the W group's most favorable policy).

The assumption implies that the size of the B majority matters for the policy outcome; a twoone B majority implies a different policy from a three-zero B majority⁶. The specifics of the policy outcome formulation do not affect the qualitative nature of the results, as we discuss below.

The ex ante expected utility of a W constitution writer is then equal to:

$$U_w = (1 - p_0 - p_1)\overline{r} + p_1 u_0 + p_0 \underline{r}, \quad \overline{r} > u_0 > \underline{r}$$

where p_j denotes the probability that j council representatives belong to the W group at the interim stage. The choice of electoral rules (the constitution) chosen by the W voters will determine the value of p_0 and p_1 .

Summarizing, the timing of events is as follows:

- 1. The electoral rule is chosen by the W group;
- 2. New B voters join the polity and elections determine a given composition of the council;
- 3. Payoffs realize.

2.2 Electoral rules and ex ante expected utilities

With an eye to the case of American cities, we now study two alternative electoral rules. The first one, referred to as representation "at-large" (AL), allocates all seats to the party that wins more than fifty percent of the votes. The second rule, referred to as "single-member district rule" (SD), requires that each candidate runs in a particular district and obtains a majority of votes within the district in order to be elected.

Given our above assumptions as to the group composition of the three districts, we immediately have that $p_1 = 0$ under the AL rule, whereas $p_0 = 0$ under the SD rule. We now compute the expected ex ante utilities of constitution writers in the W group, respectively under these two electoral rules.

2.2.1 Expected utility under the at-large rule

Under the AL rule all council seats will go to the B group if and only if:

$$B_1 + B_2 + B_3 + L_N > W_1 + W_2 + W_3.$$

⁶See Alesina and Rosenthal (1995) for an extensive discussion of this assumption and a comparison with alternatives.

Then, the ex ante expected utility of constitution writers in the W group can be simply expressed as

$$U_W^{AL} = p_0^{AL} \underline{r} + (1 - p_0^{AL}) \overline{r} = \overline{r} - p_0^{AL} \Delta,$$

where $\Delta = \overline{r} - \underline{r}$ is the constitution writers' loss from losing the majority, and

$$p_0^{AL} = \Pr(B_1 + B_2 + B_3 + L_N > W_1 + W_2 + W_3) = \Pr(\alpha > 1 + 4z)$$

is the probability of losing the majority. Substituting for z as a function of π using (1), we have:

$$p_0^{AL} = \max\left(1 - \frac{3}{\alpha}(1 - 2\pi), 0\right),$$
 (2)

so that the ex ante expected loss of constitution writers (relative to the bliss point \overline{r}) in the W group under the AL rule, is equal to:

$$L_W^{AL} = p_0^{AL} \Delta = \left(1 - \frac{3}{\overline{\alpha}} (1 - 2\pi)\right)^+ \Delta,\tag{3}$$

where we use the notation

$$x^+ = \max\{x, 0\}.$$

2.2.2 Ex ante expected utility under the single-member district rule

Under the SD rule council seats are allocated at the district level. The probability of the B group winning a majority of two seats is equal to the probability that districts 2 and 3 be won by the B group. Given that the same fraction of new B voters are allocated to these two districts, which already start with the same fraction of B voters ex ante, and given that there is a fixed majority of W voters in district 1, we immediately get that the B group obtains a two-seat majority with probability:

$$p_1^{SD} = \Pr\left(B_3 + \frac{1}{2}\alpha M > W_3\right) = \Pr(\alpha > 4z)$$

or, after substituting for z using (1):

$$p_1^{SD} = \left(1 - \frac{2}{\overline{\alpha}}(1 - 3\pi)^+\right)^+. \tag{4}$$

We can then re-express the ex ante utility of constitution writers in the W group under the SD rule, as:

$$U_W^{SD} = p_1^{SD} u_0 + (1 - p_1^{SD}) \overline{r} = \overline{r} - p_1^{SD} \delta,$$

where $\delta = \overline{r} - u_0$ is the constitution writers' loss from losing the majority, and therefore

$$L_W^{SD} = p_1^{SD} \delta = \left(1 - \frac{2}{\alpha} (1 - 3\pi)^+\right)^+ \delta,$$

is the expected loss of constitution writers in the W group under the SD rule.

2.3 The size of minorities and the choice of electoral rule

Ex ante at the constitutional stage, individuals in the W group will simply choose the electoral rule that minimizes the expected loss L_W . Our main theoretical prediction can be summarized intuitively as follows. If initially the W group commands a very large majority of votes, the constitution writers do not fear they can lose the majority under either rule, thus they are indifferent between the two rules. As the relative size of the B group increases, however, at some point it becomes preferable for constitution writers in the W group to move to AL in order to reduce the power of the B voters in districts 2 and 3 by confronting them with the whole pool of W voters, including those in district 1. Doing so allows the W group to preserve its majority as long as the fraction of B individuals does not become too large. Finally, when the fraction of B voters reaches the point that it becomes impossible to prevent their becoming the new majority, moving back to the SD rule allows the Wgroup to limit their losses. Indeed, as π becomes sufficiently close to 1/2, the risk of losing all three districts and of thereby incurring the large loss Δ makes the W group prefer a SD system which guarantees them at least 1 seat in the council - and thereby limits their loss to $\delta < \Delta$, given that in this case B voters are restricted to commanding districts 2 and 3 only. Not surprisingly, this latter motive from moving back from AL to SD disappears if the loss incurred by the minority is independent of the size of the majority, that is if $\Delta = \delta$.

More formally, we can state:

Proposition 1 (a) Both rules AL and SD involve no utility loss to W group individuals when $\pi \in \left(0, \frac{1}{3} - \frac{\overline{\alpha}}{6}\right)$; (b) if $\Delta > \delta$, then there exists a unique cut-off point $\widehat{\pi} \in \left(\frac{1}{3} - \frac{\overline{\alpha}}{6}, \frac{1}{2}\right)$ such that

$$L_W^{AL} < L_W^{SD} \text{ if } \pi \in \left(\frac{1}{3} - \frac{\overline{\alpha}}{6}, \widehat{\pi}\right)$$

and

$$L_W^{AL} > L_W^{SD} \ \ if \ \pi \in \left(\widehat{\pi}, \frac{1}{2}\right);$$

(c) if $\Delta = \delta$, then for all $\pi \in (\frac{1}{3} - \frac{\overline{\alpha}}{6}, \frac{1}{2})$ the AL rule dominates the SD rule.

Proof. In Appendix.

Figure 1 represents graphically the loss functions L_W^{AL} and L_W^{SD} where π_0^{AL} (resp. π_0^{SD}) is the size of the minority at which the expected loss under AL (resp. SD) becomes positive.

2.4 The N-districts case and extensions

2.4.1 The N-districts case

Suppose the polity's population is equally spread over the electoral districts, now numbered 1, ..., N with M individuals in each, and a council of size N. We maintain the assumption that the same two types of (ex ante) districts exist:

$$W_1 = M;$$

$$W_2 = \left(\frac{1}{2} + z\right)M;$$

where again type-1 districts are "all-W" while W_2 (type-2) districts are an ex ante identical mix of W and B. We also maintain the assumption that the district design is exogenously given as we focus on the electoral rule for given district design. There are N_1 districts like W_1 , therefore $N_2 = N - N_1$, and $N_1 < N_2$. During the interim phase a mass αM of B newcomers arrives with $\alpha \sim U[0, \overline{\alpha}]$ and $\overline{\alpha} < N$.

Now consider the possible electoral outcomes under AL and under SD respectively. Under AL only W councilmen will be elected whenever the ex post total number of W voters, $NM(1-\pi)$, is larger than the ex post total number of B voters, $\alpha M + NM\pi$. Thus, nothing fundamental changes from the three-districts case, and we now have:

$$p_0^{AL} = \left(1 - \frac{N}{\overline{\alpha}}(1 - 2\pi)\right)^+.$$

Turning to the SD rule, let us first assume that each district j of the N_2 districts receives a fraction $1/N_2$ of new comers, all of them belonging to the B group. In this case the probability that the B group wins N_2 seats on the council, is simply equal to the probability that the B voters acquire a majority of votes in any of the W_2 districts, namely

$$p_{N_2}^{SD} = \Pr\left(\frac{\alpha M}{N_2} + \left(\frac{1}{2} - z\right)M > \left(\frac{1}{2} + z\right)M\right),$$

that is

$$p_{N_2}^{SD} = \Pr(\alpha > 2zN_2),$$

where now

$$z = \frac{1}{2} - \pi \frac{N}{N_2}.$$

We then obtain:

$$p_{N_2}^{SD} = \left(1 - \frac{N_2}{\overline{\alpha}} \left(1 - 2\pi \frac{N}{N_2}\right)^+\right)^+.$$

Assume the W constitutional writers' utility u(.) to be defined over the share of seats won, where we indicate $\Delta = u(1) - u(0)$ and $\delta = u(1) - u(N_1/N)$, following the notation of Proposition 1. Once again, the constitution writers will choose the electoral rule that involves the lowest expected loss relative to the bliss point, where:

$$L_W^{AL} = p_0^{AL} \Delta = \left(1 - \frac{N}{\overline{\alpha}} (1 - 2\pi)\right)^+ \Delta$$

and

$$\begin{split} L_W^{SD} &=& p_{N_2}^{SD} \delta \\ &=& \left(1 - \frac{N_2}{\overline{\alpha}} \left(1 - 2\pi \frac{N}{N_2}\right)^+\right)^+ \delta. \end{split}$$

Then for π very close to zero, both L_W^{AL} and L_W^{SD} are equal to zero, so that constitution writers are indifferent between the two electoral rules. Next, note that for all $\pi < 1/2$, we have

$$1 - \frac{N}{\overline{\alpha}}(1 - 2\pi) < 1 - \frac{N_2}{\overline{\alpha}}\left(1 - 2\pi \frac{N}{N_2}\right),\tag{5}$$

so that as π increases away from zero, L_W^{SD} becomes positive before L_W^{AL} does; this in turn implies that for intermediate values of π , constitution writers in the W group will prefer the AL rule to the SD rule, as the former dilutes the B votes among the whole W population. Finally, as π becomes arbitrarily close to $\frac{1}{2}$, the expected loss L_W^{AL} under AL converges to Δ , whereas the expected loss L_W^{SD} converges to δ , therefore SD becomes the preferred electoral rule. We thus obtain a straightforward generalization of Proposition 1 to the case where the number of districts N is arbitrary:

Proposition 2 Consider a city of N districts, council of size N, and B newcomers' arrival αM , $\alpha \sim U[0,\overline{\alpha}]$, $\overline{\alpha} < N$, then: a) there exists a point $\pi_0^{SD} \in (0,\frac{1}{2})$ such that there is no utility loss for the W group in $(0,\pi_0^{SD})$ under any rule; b) there exists a unique cut-off point $\hat{\pi} \in (\pi_0^{AL},\frac{1}{2})$ such that expected losses under the different rules satisfy

$$L_W^{AL} < L_W^{SD}$$
 if $\pi \in (\pi_0^{SD}, \hat{\pi})$

and

$$L_W^{AL} > L_W^{SD} \text{ if } \pi \in \left(\hat{\pi}, \frac{1}{2}\right),$$

where
$$\pi_0^{AL} = \frac{1}{2} \left(1 - \frac{\overline{\alpha}}{N} \right) > \pi_0^{SD} = \frac{N_2}{2N} \left(1 - \frac{\overline{\alpha}}{N_2} \right)$$
.

2.4.2 N districts, mixed electoral systems, and risk-aversion

We now investigate the N-districts case along an important dimension: the opportunity of employing mixed electoral rules for risk-averse W voters⁷.

Consider a city with a council of size $N_{TOT} = \rho N$. Let us now assume $\rho > 1$ to allow for mixed systems: at least one representative for each single-member district and $N_{AL} > 0$ at-large representatives. Assume W's preferences to be defined over the share of seats won on the council. In a setup with risk-neutral agents, it is never optimal to have mixed systems involving both, single-district and at-large councilmen: either AL or SD offers the highest expected number of winning seats. While a risk-neutral W considers exclusively the expected seat-share and has no incentives to convexify, a risk-averse constitutional writer W may find useful to reduce the risk of running pure at-large elections when the opportunity of winning safer single-district seats is available. The following proposition presents this result more formally:

Proposition 3 Consider a city of N districts, council of size N_{TOT} , and B newcomers' arrival αM , $\alpha \sim U[0, \overline{\alpha}]$, $N_1 < \overline{\alpha} < N$. If the W constitutional writers are risk-averse with utility u(.), u' > 0, u'' < 0, defined over the share of seats won, then there is an interval (π_3, π_4) , $\pi_4 < 1/2$, and a mixed system with $N_{SD} > 0$ single district seats and $N_{AL} > 0$ at-large seats for which:

$$U_W^{AL} < U_W^{MX} \text{ and } U_W^{SD} < U_W^{MX} \text{ if } \pi \in (\pi_3, \pi_4),$$

where U_W^{AL} is the expected utility under AL, U_W^{MX} is the expected utility under a mixed system, U_W^{SD} is the expected utility under SD.

Proof. In Appendix.

Figure 2 reports a numerical example of the optimal share of single-member district councilmen as a function of the ex ante size of the minority for a stylized city of N = 12 districts with $N_1 = 3$, $\rho = 5$, and W voters with quadratic preferences, as generated by the model. The fundamental non-linearity in the choice of the electoral rule extends to the case of mixed systems (notice the ascending part of the step-function that indicates the choice of mixed systems). The parabolic curve (quadratic fit) that approximates the relation between π and the ratio of SD seats in the council (indicated as SDshare) is precisely the relation we will investigate empirically in Section 4. Figure 3 reports the expected utilities for the W agents under the different electoral rules at

⁷The fact that we observe such mixed systems in practice, may also reflect the existence of transition costs from one system to the other, or other costs (for example campaigning costs) of managing the two electoral systems, which in turn depend on the size of districts and cities.

various levels of π . The mixed system curve traces the combination of SD and AL seats that is optimal (i.e. that has the highest expected utility for W) at any given π . Over the range where such curve does not coincide with either pure SD or pure AL the chosen electoral rule includes both single-member district and at-large councilmen.

2.4.3 Uneven distribution of newcomers

In order to gain intuition in this subsection, let us briefly return to the 3-districts model employed in Section 2.1. In our analysis so far we assumed that equal numbers of new B group voters would choose to locate in districts 2 and 3. However, our reasoning and results extend to the case where a fraction f > 1/2 of new comers choose say district 2 whereas the remaining fraction (1-f) chooses district 3. This obviously does not affect the probability p_0 of the B group winning all seats under the AL rule since that probability depends only upon the overall fraction of B individuals in the population. Thus, we still have p_0^{AL} defined by (2) so that the ex ante expected loss from the AL rule, is still equal to (3).

However, the B group will only win a majority of seats on the council if it wins a majority of votes in districts 2 and 3, which in turn requires winning a majority of votes in district 3, which, of the two districts, is the harder one to secure. Therefore,

$$p_1^{SD} = \Pr(B_3 + (1 - f)\alpha M > W_3) = \Pr\left(\alpha > \frac{2z}{1 - f}\right).$$

This yields:

$$p_1^{SD} = \left(1 - \frac{1}{\overline{\alpha}(1-f)}(1-3\pi)^+\right)^+$$

with a corresponding ex ante expected loss under SD rule equal to:

$$L_W^{SD} = \left(1 - \frac{1}{\overline{\alpha}(1-f)}(1-3\pi)^+\right)^+ \delta.$$

Sufficient conditions for Proposition 1 to continue to hold are: Δ sufficiently larger than δ and $\pi_0^{SD} < \pi_0^{AL}$, that is:

$$\frac{1}{3} - \frac{\overline{\alpha}(1-f)}{3} < \frac{1}{2} - \frac{\overline{\alpha}}{6},\tag{6}$$

which implies that, as π increases from zero, p_1^{SD} becomes positive before p_0^{AL} does. Notice that now π_0^{SD} in Figure 1 becomes function of f. More generally, it is possible to show that similar sufficient conditions guarantee the non-monotonicity in the choice of electoral rules in the N-districts case with an uneven distribution of newcomers⁸.

⁸A derivation of the general case is available from the authors upon request.

2.4.4 Gerrymandering

An important practical consideration is that the design of district may itself be endogenous. In particular, the constitution-writing majority may try to "gerrymander" the districts in order to minimize the number of representatives elected by the minority. The possibility of unconstrained gerrymandering obviously makes the SD rule preferable to a majority writing the constitution. As we will discuss below, empirically this is an important consideration for American cities. How advantageous is it for the white majority to choose gerrymandering with a SD system versus an AL system depends on the nature of residential segregation in the city⁹. This is of course a known issue in the vast literature on gerrymandering.¹⁰

In the context of the 3-districts model, the constitution writers in the W group will simply choose to maximize f, that is, to pack as many new B voters as possible in one district, say district 2, in order to prevent them from ever acquiring a majority of votes in the council. In the absence of any constraints on gerrymandering (one such constraint for example would be that differentials between the number of voters across the various districts cannot be larger than a given percentage), the constitution writers will simply choose f equal to one, in which case SD will always dominate AL. However, if various constraints on gerrymandering limit the maximum f that can be achieved by the W group, then as we just saw in the subsection dedicated to the uneven distribution of newcomers the conclusions of Proposition 1 may again hold.

Finally, it is interesting to note that the possibility of gerrymandering could give rise to the same pattern seen in Proposition 1, with AL dominating for intermediate values of π and SD dominating for high values of π , even when the loss incurred by the W group is independent of the size of the B majority. That is, even when $\Delta = \delta$. To see this, let us slightly modify our basic model by assuming that constitution writers in the W group suffer from having the B group holding even one (minority) seat in the council. Then, as the size π of the B group increases from zero to 1/2, the W group will first choose the AL rule in order to dilute the B voters among all W voters. But then, as π increases further, the only way to prevent the B group from winning a majority of seats is to move from AL to SD and at the same time "gerrymander", that is pack B voters all in one district.

Even without gerrymandering the SD rule allows the W group to "waste" part of the B votes by preventing them from influencing the electoral results of district 1. With gerrymandering the

⁹Cole (1976) for instance emphasizes how at-large elections, while in principle should favor minorities which are spread out within city boundaries, in fact may not.

¹⁰On gerrymandering, see in particular Cox and Katz (2002) and Friedman and Holden (2005).

wasting (or packing) effect of SD is only reinforced: B voters cannot outnumber W voters in two districts instead of one in absence of gerrymandering. Therefore in this simplified setup, logic and predictions are basically the same with and without gerrymandering.

2.4.5 Mayors and managers

Another dimension that differentiates between American cities, is the degree of autonomy of the "executive". In a mayor-council system the executive is more autonomous from the council. Therefore, it is more difficult for the council to influence the executive process relative to the council-manager system. One way of modelling this situation is to assume that the majority needed to block the mayor is larger than the one needed to block a manager. An additional variation involves the power of the mayors which is different in strong-mayor versus weak-mayor forms of government.

Without a veil of ignorance, if the W majority always knew that it could elect the mayor it would choose a more powerful mayor. But following the same logic of above, this would not be necessarily the case if the W majority is slim and there are unforeseeable shocks to the composition of the electorate. In the empirical part we also briefly explore the choice between mayor council system and manager council systems.

3 Institutional setting and data

We begin this section with a brief review of the history of voting rights in the South. A description of the data follows.

3.1 Legal and judicial interventions on voting in the United States

There was no constitutional protection for voting and electoral participation in the United States before the Civil War.¹¹ African American individuals in state of servitude were neither granted citizenship nor, consequently, voting rights. After the war, during the Reconstruction (1867-1877), the Congress provided such constitutional protection with the ratification of the 14th Amendment in 1868 (conferring citizenship to all persons born or naturalized in the United States) and the 15th Amendment in 1870 (providing that the right of vote should not be denied or abridged on the basis of race, color, or previous status of servitude). The Enforcement Act (1870) and the Force Act (1871) ensured additional legislative detail, among other things introducing federal oversight over

¹¹We refer to the United States Department of Justice, Civil Rights Division, Voting Section for further details and reference for this section.

elections. Such measures effectively induced an enlargement of the electoral franchise to the black minority, both in the South and in the rest of the country¹². Around 1872 more than 300 Southern black legislators were holding elected offices.

However, after the 1877 compromise, the demilitarization of the South and the ensuing "Redemption", Southern whites succeeded in reimposing pre-war political equilibria. The introduction of a series of legal procedures, color-blind on paper but anti-black in practice, such as poll taxes, literacy tests, "grandfather clauses", "understanding clauses", vouchers of "good character", and disqualification for crimes of "moral turpitude" achieved the substantial disenfranchisement of the black minorities in the South. In addition, white majorities extensively entertained the practice of "white primaries"¹³. By the early 1900's the number of Southern black legislators was back to zero: an early exemplification of the endogeneity of political institutions to sudden shifts in the electoral franchise (see Kousser, 1999). According to Woodward (2002) in Louisiana registered black voters were 1,342 in 1904, down from a peak of 130,334 in 1896. This coincided with the appearance of extensive Jim Crow legislation at the State level in the South. Until the mid-1960s the number of Southern black legislators remained close to zero. This coincided with a seemingly marginal role played by the Supreme Court in the active defense of the 15th Amendment.¹⁴

It was only from the mid-1960's that the Supreme Court started an active monitoring of electoral

Only with the 19th Amendment to the Constitution, which became law in 1920, women obtained the right to vote in all elections. Constitutional amendment proposals for the extension of the electoral franchise to women had begun in 1878 and were proposed in every session of the Congress for the following 40 years. Some States already had laws enabling women to vote before 1920. Examples are Utah, Colorado, Idaho, and Wyoming, the first State in the Union allowing women to vote in 1890. The States of New York, Massachusetts, New Hampshire, and New Jersey allowed women to vote at the end of the 18th century, but between 1777 and 1807 they revoked those clauses.

Also Asian, Native American and Mexican individuals were not allowed to vote, not being recognized as U.S. citizens. In 1924 Native Americans were granted citizenship and in 1948 the last state laws denying vote were overturned. Asians were able to obtain full citizenship after the progressive overturning of the Chinese Exclusion Act of 1882 completed in 1952.

¹³See Myrdal (1944) for a detailed account. According to Woodward (2002, p.85) "the state-wide Democratic primary was adopted in South Carolina in 1896, Arkansas in 1897, Georgia in 1898, Florida and Tennessee in 1901, Alabama and Mississippi in 1902, Kentucky and Texas in 1903, Louisiana in 1906, Oklahoma in 1907, Virginia in 1913, and North Carolina in 1915." Primaries were not open to racial minorities and were effectively used to skim out black voters, hence the appellation "white primaries".

¹⁴However, there were exceptions. In Guinn v. United States, 238 U.S. 347 (1915), the Court ruled against a Oklahoma "grandfather clauses" provision, in Smith v. Allwright, 321 U.S. 649 (1944), the Court ruled against Texas' "white primaries", and in Gomillon v. Lightfoot, 364 U.S. 339 (1960), the Supreme Court found unconstitutional the practice of gerrymandering in the city of Tuskugee (Alabama).

¹² All voters were white male according to the Naturalization Law of 1790.

participation provisions and apportionment of state legislative districts. In Baker v. Carr, 369 US 186 (1962), the Court ruled against malapportionment. In a series of cases (Wesberry v. Sanders, 376 US 1 (1964), Reynolds v. Sims, 377 U.S. 533 (1964), Fortson v. Dorsey, 379 U.S. 433 (1965)) the Court ruled in the direction of re-equilibrating the weight of rural and urban votes, favoring urban minorities. At the same time the federal government started playing a much active role as well. President Lyndon Johnson ratified the 24th Amendment of the Constitution¹⁵ (1964) and signed into law both the Civil Rights Act in 1964 and the Voting Rights Act in 1965. LBJ relied on a coalition of Northern democrats and republicans to pass the act against the opposition of Southern democrats. The Senate passed the Act in a 77-19 roll call vote (47 democrats and 30 republicans, 17 Southern democrats and 2 republicans opposed the bill).

The goal of the VRA is to remove strong obstacles in voting registration procedures for racial minorities. Section 2 of the Voting Rights Act included a broad reassessment of the principles embedded in the 14th and 15th Amendments. It deemed illegal the use of poll taxes, literacy tests, and the requirement of fluency in English for voting eligibility. Section 5 introduced strict requirements of pre-clearance (by the District Court for the District of Columbia or the U.S. Attorney General) of new voting procedures ¹⁶. The bill authorized federal supervision of black voters' registration in Alabama, Georgia, Louisiana, Mississippi, North Carolina (in 34 counties), South Carolina, and Virginia (Woodward, 2002). In South Carolina v. Katzenbach, 383 U.S. 301 (1966), the Supreme Court upheld the Constitutionality of the Act. In Allen v. State Board of Elections, 393 U.S. 544 (1969) pre-clearance conditions were specified for a series of "tests or devices" of minority vote dilution, including explicitly changes to at-large elections from single-member district elections.

As a consequence of the Voting Rights Act, the number of registered minority voters as a fraction of voting age population doubled and in some cases tripled in Alabama, Georgia, Louisiana, Mississippi, and Virginia between 1965 and 1988 (Grofman, Handley and Niemi, 1992). Amy (2002) reports that "the number of black elected officials in the United States grew an average 16.7 percent

¹⁵The amendment outlawed the poll tax in federal elections. Virginia ratified the amendment in 1977, albeit the ratification process was completed on January 23, 1964 (by 38 States). The amendment was ratified by North Carolina in 1989. The amendment was rejected by the State of Mississippi (and not subsequently ratified) in 1962.

¹⁶Section 5 precisely indicates which political organizations are covered by the act through identification of specific parameters. States fully covered under the 1975 renewal of the Voting Rights Act are Alabama, Alalska, Arizona, Georgia, Louisiana, Mississippi, South Carolina, Texas, and Virginia. California, Florida New York, North Carolina, and South Dakota are only partially covered in specific counties and Michigan and New Hampshire in specific townships. See Data Appendix for details.

a year between 1970 and 1977, from 1469 to 4311" $(p.129)^{17}$.

In the light of continuing racial polarization in 1970, 1975, and 1982 the Congress introduced amendments to the Voting Rights Act extending Section 5 of 5, 7, and 25 years and addressing the removal of persistent obstacles to effective voting by the newly registered racial minorities (like gerrymandering, annexations, at-large elections, multi-member districts, and other "structural changes" to prevent blacks from voting through electoral dilution). The Supreme Court followed suit, for example in White v. Regester, 412 U.S. 755 (1973) and, with respect to dilution associated with at-large elections, in Thornburg v. Gingles, 478 U.S. 30 (1986). During the 1980's and 1990's the federal government and the Supreme Court tended to diverge more frequently with respect to affirmative intervention in promoting minorities' political enfranchisement (particularly, with respect to affirmative gerrymandering)¹⁸.

From this brief historical excursus, we need to remember two points germane to our empirical analysis:

- 1) Until the mid-sixties white majorities did not have to worry about black vote in the South; only with the Voting Act of 1965 blacks were really a political block to reckon with electorally.
- 2) The implementation by the Courts of the Voting Rights Act also took up the issues of the choice of electoral rules, precisely to avoid choices (like at-large elections) that would have favored the white majority. Thus, any attempt of the white majority to engage in the kind of strategic choices implied by our theoretical model would have to face potential challenges from the Courts.

¹⁷In 1999 according to the Joint Center for Political and Economic Studies the total number of black elected officials was 5938 in the South (respectively 8936 in all U.S.), of which 340 were city mayors (resp. 450 nationwide), 2677 members of municipal governing bodies (resp. 3498 nationwide). There were no black senators in 1999 and 19 representatives form the South (39 black representatives nationwide).

¹⁸In 1980 the Supreme Court imposed the requirement of proof of "racial discriminatory purpose" in vote dilution cases (Mobile v. Bolden, 446 U.S. 55, 1980). This was rectified by a 1982 Congress Amendment, dispensing from such proof. The Supreme Court substantially challenged "affirmative gerrymandering" in Shaw v. Reno, 509 U.S. 630 (1993) and Holden v. Hall, 512 U.S. 874 (1994) among the others. Under President Bill Clinton the National Voter Registration Act (also known popularly as the Motor Voter Act of 1993) aimed at strongly promoting voter registration (for example, through the department of motor vehicles structures, unemployment, and welfare bureaus). More recently the Help America Vote Act of 2001 has shifted back to individual States most of the supervisory power over the quality of electoral franchise. Voting Rights Acts renewal hearings are due in 2007.

3.2 Data and summary statistics

This section briefly reviews the main variables employed in the empirical analysis. We refer the reader to the separate Data Appendix¹⁹ for details on variables definition, construction and sources. We gathered two sets of data: one including characteristics of city governments and their institutional details; the other including demographic, economic, and geographic characteristics of US cities. We collected information on US municipal governments characteristics for the period 1930-2000, at 10-year intervals, from the Form of Government Survey and Municipal Year Book by the International City/County Management Association (ICMA) in Washington D.C.

ICMA is a professional organization of city managers and administrators publishing local government data since 1914 and a well-recognized scholarly source. ICMA survey data have been employed in a number of papers, including Baqir (2001), Sass and Pittman (2000), DeSantis and Renner (1992) among the others.

From the various issues of the ICMA surveys²⁰ we collected information on electoral rules and forms of government for each municipality, including: council size; number of district-awarded council seats; form of government; number of councilmen belonging to different racial groups currently sitting in the council; mayor's veto power over council resolutions; mayor's vote restrictions in council resolutions; mayor's length of term in office; indicators of the presence of referendum, initiative or recall. Particularly, with respect to electoral rules we constructed two single-district variables: (i) SD, a dichotomous variable equal to 1 if all councilmen are elected by single district, 0 otherwise; (ii) SDshare, a continuous variable defined as the fraction of councilmen elected in single districts. In 2001 about 65.9 percent of the cities in the sample presented only at-large-elected councilmen, about 14.8 percent presented only district-elected councilmen. The remaining cities presented some combination of the two types of rules (mixed systems), with councils consisting of a fraction of councilmen representing specific geographic areas and the others "representing the whole city".

From the decadal issues of the Bureau of the Census' of Population we collected information on total population, racial groups sizes, median income, and geographic characteristics of Places

¹⁹Due to space limitations we produce the Data Appendix in a separate document, available on request. Please refer to the authors' webpages for a downloadable version of the Data Appendix.

²⁰Data from 1980 onward are available in electronic format; data before 1980 needed to be collected and entered from hard copies. For this reason we decided to collect data before 1960 only for the South, since it is in the South where the effect of the Voting Rights Act is more relevant and should show larger differences before and after the mid-1960s.

and Minor Civil Divisions (MCD's)²¹. Particularly with regard to racial composition, from 1930 to 1970 the data available allow for a breakdown into three groups: white, black, and other races (we did not distinguish between foreign-born or native). From 1980 the Census allows for a more refined breakdown (in general the breakdown includes at least Whites, Blacks, Hispanics, Asians, Pacific Islanders, and Native Americans). Since our empirical analysis runs from the thirties to the nineties, for consistency we used the three-groups breakdown (White, Blacks, others) for the entire sample. Our variable of interest is the size of non-whites (we also reproduced all our result using blacks instead of non-whites, with virtually no changes in the results). ICMA and Census data were subsequently merged on the basis of geographic identifiers and FIPS codes (unique identifiers) whenever available or matched by city name and individually checked. Details on the procedure are available in the Data Appendix.

A final caveat. ICMA surveys present different coverage depending on the year. We review their representativeness in terms of population characteristics vis-a-vis the corresponding entire Census population of places and MCD's in the Data Appendix. The bottom line is that the sample of US cities collected by ICMA is representative of the total population of relatively large cities, above 2,500 inhabitants, and less representative of the full population of the Bureau of the Census Places and Minor Civil Divisions (MCD's). This is the reason why in what follows, we always report results for the entire available sample and for a subsample of cities above the threshold of 2,500; the results are in general almost identical. We were also able to obtain the full lists of cities sampled from ICMA for the last survey in year 2001 and we verify the absence of any response selection in the survey²². In the Appendix tables A1 and A2 we report summary statistics for the key variables of interest for the sample of all US cities and for the sample of Southern cities.

4 Empirical results

The empirical investigation in this section focuses on the main prediction of our model, namely that an increase in the size of the minority makes AL preferable over SD if initially the minority group (the B voters) represents a sufficiently small fraction of the overall population, whereas the opposite is true if initially the minority group represents a sufficiently large fraction of the overall population. In other words, the preference of constitution writers for AL over SD, increases and then decreases with the initial size of the minority group.

With the aim of testing a model of endogenous choice of checks and balances, Aghion, Alesina,

²¹Definitions and references in the Data Appendix.

²²See Data Appendix.

and Trebbi (2004) employ data on a vast cross-section of countries, including democracies and non-democracies. American cities offer a potentially "cleaner" sample for testing the hypothesis of constitutional endogeneity for several reasons. First of all, American cities are much more similar to each other than a cross-section of countries ranging from advanced democracies to developing dictatorships. Moreover US cities present enough time-series variation to account for time-invariant unobserved heterogeneity in the data, arguably a potential source of bias in cross-sectional analysis. Second, the racial divide (mostly white/black historically, whites/blacks/asians/hispanics more recently) has been a prominent feature of the institutional debate and political choice in US cities²³ and the assumption of bloc-voting within racial lines has empirical foundation. Third, the evolution of minority voting rights and the Civil Rights movement in the sixties suggest a transformation of the nature of democratic institution in US cities. Before the Voting Rights Act of 1965, black voters in the South were largely disenfranchised, consequently the choice of electoral rules was rather irrelevant from a race-relation point of view. From the mid-sixties onward white majorities had to cope with black voters; therefore they had an incentive to adopt electoral rules and forms of governments that minimized black influence. This episode allows us to perform additional robustness checks of our model of endogenous evolution of electoral institutions.

4.1 The choice of electoral rules

Empirical Strategy - The empirical strategy that we employ in Table 1 and in the majority of the following tables is a simple, yet flexible, linear (in the coefficients) parametric two-way panel model of the choice of electoral rules in which we account for unobserved, time-invariant heterogeneity at the city level and for time-specific effects. Proposition 1 hypothesizes a non-monotonic, U-shaped relationship between either SD or SD and π , which provides intuitive appeal to the choice of fitting a quadratic relationship between SD or SD and π^{24} . For each city i in year t let us define the political variable of interest SD and π^{24} . (the fraction of councilmen elected by ward or district), the relative size of the minority²⁵, π_{it} , a vector of $(k \times 1)$ controls X_{it} and the two-way

²³US cities are not the only example of local politics influenced by race relations. For a discussion of electoral rules and racial politics in elections in India see Pande (2003).

²⁴ Further, simple non-parametric evidence is provided in what follows. A third-order polynomial produced a very similar fit as the quadratic model we report. The main difference recurred for high levels of π , where the race of the charter writers could be non-white. Higher-order polynomials produced a worse fit than the quadratic.

²⁵Notice that the theoretical restriction $\pi < 0.5$ is satisfied in the data, as more than 90 percent of cities are below $\pi = 0.361$ for the whole sample of American cities and below $\pi = 0.433$ for the South.

error component as $u_{it} = \alpha_i + \delta_t + \eta_{it}$. We specify²⁶ the following equation in levels:

$$SDshare_{it} = \beta_0 + \pi_{it}\beta_1 + (\pi_{it})^2 \beta_2 + X'_{it}\gamma + \alpha_i + \delta_t + \eta_{it}$$
 for $i = 1, ..., N$ and $t = 1, ..., T$. (7)

Controlling for city-specific unobserved characteristics is relevant to our empirical strategy. Historical, geographical, and cultural conditions explain much of the variation in political institutions at the city cross-sectional level (about 67 percent of the variation). However, such conditions are often difficult to measure directly and would bias, if omitted, any inference concerning the role of changes of racial composition of the city in the choice of electoral rules. Employing within-city variation allows us to account for such unobserved heterogeneity and estimate consistently the vector (β_1, β_2) . Time-specific effects are similarly useful in accounting for across-the-board effects, such as federal legislation, that again need to be controlled for, especially in the post-1965 period²⁷ when indeed legislation was extremely active. We address the issue of serial correlation in the error component η by relaxing the assumption of independence and clustering at the city level. Conditional heteroskedasticity of unknown type is also accounted for.

Identification - The most likely source of reverse causation affecting (7) is endogenous sorting across municipalities driven by more favorable electoral rules. Minority voters may move towards cities in which they have better chances of representation, and similarly white voters may move out of cities with excess minority representation. Hence, Tiebout sorting would predict a correlation between changes in city racial composition and in electoral rules of the opposite sign to what predicted by our model, dampening the least squares estimates. It is fundamental for our analysis that such bias would be of negative sign. Specifically, suppose that a city changes its electoral rule in favor of white voters against black voters. Then the percentage of the latter should go down as a consequence of Tiebout sorting (and possibly the white group could increase in number reducing the fraction of blacks even further). However, we show below that, as the share of blacks increases, electoral rules turn against them. This means that the estimates presented below need to be interpreted as lower bounds of the effects the theory predicts and the quantitative relevance of the endogeneity of the electoral rule is underestimated. Correcting for the bias arising from endogenous sorting would increase the quantitative relevance of our results.

A final issue in the empirical strategy concerns the timing of the Voting Rights Act. Table 1 is divided in two parts: for the period before and after the Voting Rights Act of 1965²⁸. The first year

²⁶The same specification is also employed for SD. However in that case we assume a logistic distribution of η .

²⁷ Formal F-tests for this specification support the use of a two-way setup. Both groups of fixed effects are jointly significant in every specification.

²⁸Note that one may want to exclude cities in which whites are a minority. There are very few of those and

for which complete survey data from ICMA are available after 1965 on electoral rules (and forms of government) is 1967, which we take as the dividing line for pre- and post-Voting Rights Act and we match to the 1970 Census data. The non-monotonic relation should emerge only in case of an enfranchised minority. From the time of its introduction, the Voting Rights Act represented a sudden extension of the political franchise to blacks. We employ such date as an informative source of variation for institutional manipulation, particularly in Southern cities.

Results - The first four columns of Table 1 refer to the sample of Southern cities²⁹. Column (1) shows the basic specification including all cities. Column (2) focuses on cities above the 2,500 threshold (remember that the ICMA sample is more representative for cities above this size) columns (3)-(4) include additional controls for city size, median income, and a deterministic time trend at the State level. The last two columns show the same regressions for the sample of all US cities.

The model calls for a negative linear and a positive quadratic coefficient on the share of the non-white minority; as this share increases, at-large elections become more desirable up to a point in which the voting minority is so large that the majority is better off by "packing" minority votes through single-district elections. The signs of the coefficients are consistent with this story. Looking for instance at column (1) the estimated coefficients imply that this U- shaped curve reaches a minimum at about 29.2 percent (0.292 = 0.885/3.028) non-white minority. (Note that 66.7 percent of the sampled cities in year 2000 were below this level). The last two columns show that when we look at the US as a whole, the sign of the coefficients is the same as that for the South, but the size of the coefficient is smaller in absolute value, roughly half, suggesting that these racial effects are stronger in the South. To gauge quantitatively the size of the two effects, one can start observing the empirical distribution of the size of minorities in Southern cities. Consider as a benchmark the cross-sectional distribution of minority sizes in year 2000 (but likewise for all the decades 1970-1990) for those cities employed in the column (1) sample. The first quartile (Q1) for the fraction of minority is 9.76 percent and the third quartile (Q3) is 34.86. At Q1, given estimated coefficients in column (1) of -0.885 and 1.514 (with clustered standard errors respectively 0.308 and 0.475), an increase of one standard deviation of minority sizes (16 percent) implies a reduction of -5.56 percentage points $(-0.0556 = -0.885*0.16+1.514*(0.2576^2 - 0.0976^2))$ of the fraction in addition even when whites are a minority in terms of number of inhabitants, demographic factors and vote participation patterns may still make them a majority as active voters (see Amy 1993, p.125 for an example). For

this reason it is unclear which cities to drop from the sample. We tried a few experiments and our results appear

robust.

²⁹ As for all the rest of our empirical analysis we exclude from the sample those cities for which we have information that the change of structure of government is the result of court mandate or State Law. ICMA data provide partial information with this respect.

of single-district seats. This is equivalent to about one seat switching from single-member district to at-large in a council of 18 seats. At Q3, the same increase of one standard deviation would instead produce an increase of about +6.6 percentage points in the fraction of single-district seats. This would be equivalent to about one seat switching from at-large to single-district in a council of 15 seats. These two estimates appear quantitatively reasonable. In order to evaluate the size of these effects one has to remember that the Voting Rights Act itself imposed limits on how much cities could switch to AL systems³⁰. In other words, without Supreme Court involvement, these effects would have been surely larger, even if possibly not as large as the disenfranchisement of the 1877-1900.

The bottom panel shows regression for the sample of Southern cities before the VRA, for the period 1930-1970³¹. Here the coefficients on the size of the minority and its square are statistically zero. This is consistent with our hypothesis that before the Voting Act electoral rules were unaffected by the city racial composition, since racial minorities were almost completely disenfranchised.

Table 2 presents estimates employing a discrete dependent variable, SD, and a conditional logistic estimator grouping observations at the city level. This specification corresponds to what part of the applied literature calls fixed effects (or conditional) logit model. The implications of Table 1 carry over to this specification consistently with the predictions of Proposition 1. Given that the likelihood contributions of cities which do not change their electoral rule are zero, the number of observations is smaller than in Table 1. For what follows we prefer to limit ourselves to the analysis of the continuous variable SDshare given the greater flexibility allowed by the continuity of the dependent variable.

Time persistence is an important characteristic of political systems, therefore we employ a standard dynamic panel technique, through first differencing and application of the Arellano and Bond (1991) GMM estimator, in Table 3 to account for this feature. This procedure has the dual advantage of enriching our basic specification of a dynamic component and addressing the issue of endogeneity of size of the minority through the use of lags of the exogenous variables (the time fixed effects), endogenous variables (city population and fraction of the minority), and the dependent variable. The specification we employ is:

$$SDshare_{it} = SDshare_{it-1}\theta + \beta_0 + \pi_{it}\beta_1 + (\pi_{it})^2\beta_2 + X'_{it}\gamma + \alpha_i + \delta_t + \eta_{it}.$$

 $^{^{30}}$ See below for further details.

³¹The panel observation we indicate as 1970 indeed employs information on 1967 ICMA data, matched with 1970 Census demographic variables. We also repeated all the analysis matching the Census with the 1972 ICMA data with very similar results. We opted for 1967 because of better coverage and vicinity to 1965, the actual date of enactment of the bill.

Together with a significant autoregressive component (θ about 0.3 in column (1), panel a) the first three columns show the same patterns of coefficients on the share of minority variable as Table 1. The minimum in this U curve is reached at a fraction of the minority of about 33.8 percent. The coefficients β_1 and β_2 for the size of the minority are in the same order of magnitude of our previous results in Table 1, but about two times larger ($\beta_1 = -1.644$ and $\beta_2 = 2.645$ in column (1) with one-step robust standard error respectively 0.712 and 1.002). Quantitatively a stronger result, this would imply a change of 1 seat from single-district to at-large in a council of 9 at Q1 (about -11.27 percentage points) and a change of 1 seat from at-large to single-district in a council of 10 at Q3 (about +9.97 percentage points). Again we also find no significant role for racial composition in the pre-Voting Rights South (panel b). Finally, we need to note that due to the lag requirements of the model, we find ourselves confined to a smaller sample (especially for the all US sample, which is limited to the post-1980 period and for which we can employ at most one lagged difference).

The specification checks for the dynamic model are reported at the bottom of each panel of Table 3. For Columns (1) and (2) the second order serial correlation p-values of the one-step procedure does not raise concerns over the validity of the instrument set, but the overidentification test's p-value obtained from the GMM two-step procedure seems low (although not granting rejection at any confidence level for the South and not at 5 percent for all US) given the low-power properties of such tests. However, the consistency of the standard linear model and this simple dynamic extension are source of reassurance.

4.2 Additional nonparametric evidence on the choice of electoral rules

Simple nonparametric evidence supports the main prediction of the model as well. We expect to observe two basic regularities in the data. First, the slope of a within regression of the single-district variable on the fraction of the minority (or the fraction of blacks) should be increasing in subsamples where the average minority size is increasingly higher. Second, we would expect statistically significant coefficients of negative sign to appear at relatively small values of the fraction of the minority (where the downward-bending part of the U-shaped parabola is steeper) and statistically significant coefficients of positive sign to appear at relatively large values of the fraction of the minority (where the upward-bending part of the U-shaped parabola is steeper). A flat and insignificant relationship should appear in the middle range. We borrow a simple modification of locally weighted scatterplot smoothing (lowess) from Imbs and Wacziarg (2003) and run a series of within-city regressions in the relevant interval of minority sizes $\pi \in [0.05, 0.55]$ employing a symmetric bandwidth of half a cross-sectional standard deviation of minority size (17/2 = 8.5

percent). Again we focus on the South of the United States for the period post- and pre-1967. Specifically for each subsample we estimate:

$$SDshare_{it} = \beta_0 + \pi_{it}\beta_1 + \alpha_i + \delta_t + \eta_{it}.$$

At increments of 1/5 of a percentage point of minority fraction (i.e. 0.002) we register the withincity slope (β_1) and its t-statistic. We then regress the estimated slopes and the t-statistics against the corresponding mid-sample fraction of the minority. In both regressions a positive coefficient on the mid-sample fraction of the minority would confirm each of the two hypotheses discussed above. Table 4 reports results for both post- and pre-1967 for non-white minorities and confirms our predictions.

As expected, coefficients move from being prevalently negative at low levels of π^{32} to being prevalently positive at higher levels of π (around 1/2). Over the interval³³ $\pi \in [0.05, 0.22]$ the average coefficient for nonwhites in the post-1967 South is equal to -0.601 and gives an estimate that is larger but comparable to the effect of the parametric estimate at Q1 (for an increase of 16 percent the change in single-district is -0.102 versus -0.0556 of the F.E. parametric model and -0.1127 of the dynamic panel); the same holds for the average coefficient in the interval $\pi \in [0.38, 0.55]$ ($\beta_1 = 0.857$) comparable to the parametric effect at Q3 (0.145 versus 0.0660 in the F.E. model and 0.0997 in the dynamic panel). A within regression in such small subsamples (due to the small bandwidth) is demanding, but nonetheless the main nonlinearity is detectable. However, we detect large fluctuations in the coefficients due to the varying (and small) number of changes in electoral rules in each subsample. We observe relatively larger (in absolute value) t-statistics mostly around the extrema of the interval of minority sizes (negative at low levels of π and positive at large levels of π) and generally insignificant results otherwise.

Finally, a nonparametric illustration of the U-shaped relation between single-member district rule and the fraction of the minority is presented in Figure 4. We report graphically the predicted values of a locally weighted regression with a chosen bandwidth of 0.8 and of 0.3. The regressions employ as dependent variable the residuals from column (2), Table 1, for the post-1970 sample in order to partial out between variation. This additional nonparametric evidence confirms what reported in Table 4 and the basic nonlinearity of the model. As expected, the locally weighted regression with the smaller bandwidth presents a less smooth picture than what predicted by the

 $^{^{32}}$ Notice that flats at low values of π are justified by the relative equivalence of at-large and single-district rules in cases where minorities would not gain representation under any of the two rules.

 $^{^{33}}$ Bounds for the intervals of π are chosen to divide in three equal parts the support for the downward, flat, and upward part of the curve.

regressions with the higher bandwidth, but both follow quite closely the fitted parametric parabola. Only for ranges of minority sizes larger than 50 percent the picture is less clear, both because of the small frequency of data points and because the predictions of the model could be reversed in this range of data³⁴.

4.3 Electoral rules and minority representation

Our basic story holds that electoral rules affect the ratio of minorities elected differently. This is the reason why the constitutional writers choose different rules in the first place. Crucially, the ratio of non-white council members should display dependence on the electoral rules in order for the fundamental tenet of our analysis to be verified. Moreover, different rules should have different effects on minority representation at different minority sizes. By quantitatively documenting the correlation between electoral rules and minority representation, in this section we provide evidence that both statements are verified by the data and that the estimated effects move in the direction our model presumes and rationalizes.

The representational ratio (RR) is the fraction of minority councilmen in a council divided by the fraction of the population that belongs to the minority and is available for our all-US cities sample in year 1980, 1990, and 2000³⁵. A large number of empirical political scientists have employed the representational ratio as the typical measure of the degree of "proportionality" of an electoral system (i.e. if composition of population racial group maps one-to-one into the racial composition of the legislative body). We regress RR on our variable of interests, the single-district rule variable. Table 5 reports the results. The null hypothesis that the electoral rule adopted by a city has no association with the representational ratio is soundly rejected in both a pooled cross-sectional regressions (Panel a) and in fixed-effect regressions in which time invariant city-specific unobserved heterogeneity is accounted for (Panel b). All specifications include year fixed effects and a set of standard controls for city size (log population) and income levels (log household median income in 1990 dollars) and we apply the same clustering as Table 1. Looking at columns (1) and (2) for the South and (3) for the whole country, single-district rules substantially increase the chance of minorities to be proportionally represented at the municipal level. Recalling that the fraction of single-district seats, SDshare, is defined over the [0, 1] interval, our results in column

³⁴Unfortunately the scarcity of observations precludes the possibility of testing for a symmetric " ω " in the proper minority-majority part of the graph (i.e. $\pi > .5$).

³⁵Very few cities for the all US sample present representational ratios of minorities of more than 1, indicating over-proportional representation. Even less of them are present in the South. In order to limit the role of these outliers we limit the representational ratio to be smaller than 5.

(1) imply an average increase in the RR of the city council between 13 (in panel a) and 35.4 (in panel b) percentage points from switching from a fully at-large rule to a fully single-district rule³⁶. This is a quantitatively substantial effect: each black or minority vote has something less than 1/3 more weight in terms of electoral representation under single-district than under at-large elections. Both our cross-sectional and fixed-effect analysis provide quantitatively similar evidence and, as one would expect, such results are quantitatively stronger in the more segregated South. Finally, let us note that the correlations presented in columns (1)-(3) identify a causal effect of the electoral rule on the representational ratio only under the strong exclusion restriction that the fraction of the minority does not have an independent effect on RR.

In columns (4)-(7) we provide evidence that the impact of the single-district rule on the representational ratio is actually non-monotonic in the size of the minority by including an interaction of the single-district variable and the fraction of non-whites. The size of the non-white group is included in order to account for any direct effect of the fraction of the minority on the representational ratio and to avoid attributing such direct effect to the interaction term. Moreover this allows us to relax the strong exclusion restriction of columns (1)-(3). At low levels of minority size both at-large and single-district should be indistinguishable in warranting representation: minority are just too small to achieve representation under any rule. However, as the minority size increases single-district will offer better chances of representation to geographically segregated minorities vis-a-vis at-large. Such effect will diminish, however, when the minority becomes so large that some district votes (those beyond simple majority in the district) will be wasted. This implies that the sign of the coefficient should be negative on the interaction term. In panel a) columns (4)-(7) present interactions with the predicted sign that are significant at standard confidence levels and reject the absence of a non-monotonicity. Moreover, single-district maintains his expected positive effect, while the fraction of minority has a positive coefficient. The picture in the fixed effect analysis in panel b) is less clear, primarily because the required variation in the data is a contemporaneous change over three dimensions: electoral rules, fraction of minorities, and number of minority councilmen. Albeit our data set is rich, this requirement is probably too stringent.

We are not the first to observe that at-large election favors the white majority and our results are consistent with a substantial body of Political Science literature on the matter. For instance Amy (2002) writes that "the system of voting in at-large elections often makes it virtually impossible for minority candidates to get elected. At-large elections require candidates to get a majority or

³⁶Virtually identical results are obtained when we define the left hand side as fraction of non-white concilpersons over the fraction of non-white population. We use specifically the black group in order to make our results more comparable with the previous literature.

plurality of the vote to win, which usually allows a white majority to take all seats and to deny minorities any representation at all." (p. 150) ³⁷. Sass and Pittman (2000) also provide panel data evidence on the effect of electoral rule on minority representation reporting a representational ratio differential of 36 percent, quite comparable with our linear estimates. Our results extend to more recent data and a substantially larger sample of cities. We are not aware of previous empirical studies pointing at the non-monotonicity in the effect of single-district rules on minority representation.

4.4 The Voting Rights Act and electoral rules

This section investigates further how the Voting Rights Act imposes a constraint on the constitutional choice of the white majorities. The Voting Rights Act not only removes (and has removed) obstacles to minority voting registration. Any jurisdiction covered under Section 5 of the Voting Rights Act has the duty of obtaining pre-clearance for any change concerning voting from the office of the Attorney General through the Department of Justice or the United States District Court for the District of Columbia. Every change proposed is individually reviewed from the Department of Justice and cleared³⁸ "if the change does not lead to a retrogression in the position of minority voters with respect to the effective exercise of the electoral franchise". Case by case clearance is based on the study of the most recent Census and electoral data available and through interviews to concerned parties.

The implementation (both by Law and through the Courts) of the Voting Rights Act has been extremely successful, but it is hard to presume it has been perfect and definitive. The very fact that the VRA has been repeatedly renewed over time indicates that pressures towards distortion of voting institutions are still present and perceivable (the VRA is due for renewal in 2007). Riker (1984) offers a brilliant account of a camouflaged litigation in a council-manager redistricting dispute (albeit in a different legal context), an example of how political institutions may still be distorted in favor of an incumbent majority even in such situations. We believe our analysis detects such pressure in the form of systematic strategic changes in electoral rules under the current legal constraint. The estimated dimension of the changes detected seems not so large to lead to a severe under-representation of blacks. Severe under-representation would raise legal highbrows and court challenges and, ultimately, legally-imposed changes in the electoral rule (we exclude known

³⁷ For similar views see Berry and Dye (1987). For empirical cross-sectional analysis see Karning and Welch (1982), also cited in Amy (2002).

³⁸Information concerning objected changes can be found in the motivation letters available at http://www.usdoj.gov/crt/voting/sec_5/obj_activ.htm.

instances of this type from our analysis).

It is relevant to investigate how our results would change depending on the VRA coverage. We first investigate how the sample moments of the data evolve over time in fully and partially covered States. Then we repropose Table 1 results conditional on VRA coverage.

Table 6 reports median values for ethnic fragmentation, fraction of blacks, and fraction of non-white minority for 10 years intervals between 1970 and 2000 in the South for States fully and partially covered by the VRA. Notice that the basic non-monotonicity in the choice of electoral rules is present. At the median cities changing electoral rule in each of the 1970-80, 1980-90, 1990-2000 decades experience an increase in the size of racial minorities. However, cities decreasing in the fraction of single-member district councilmen tend to have smaller minorities than cities increasing in single-district rule. This appears consistent with our previous findings and indicates some degree of manipulation of the electoral rule in the VRA-covered States.

Finally, the coverage on the Voting Rights Act is endogenous: the loci of greater potential conflict are those to which the VRA applies in full coverage. They are also the ones where the effects we detect are clearer. Table 7 reproduces the post-VRA result of Tables 1 and 3 for those cities belonging to fully VRA-covered States and shows, especially for the basic panel model, greater significance and quantitatively larger coefficients. In column (2), panel a), the linear coefficient increases of about 48 percent, the quadratic 18 percent vis-a-vis the benchmark reported in column (1). At Q1, given estimated coefficients in column (2) of -1.307 and 1.781 (with clustered standard errors respectively 0.393 and 0.558), an increase of one standard deviation of minority sizes (16 percent) implies a reduction of -10.79 percentage points of the fraction of single-district seats. This is equivalent to almost one seat switching from single-member district to at-large in a council of 9 seats. At Q3 the increase of one standard deviation would produce an increase of about +3.514 percentage points in the fraction of single-member district seats.

There also seems to be some evidence that the Voting Rights legislation has been progressively more effective in detecting strategic electoral manipulation. The estimated coefficients for column (2) in Table 7 for the period 1970-80 only are -1.314 and 2.409 respectively for the linear and quadratic term. The same estimates drop to -0.401 and 0.192 when restricting the sample to the period 1980-90 and to -0.589 and 0.876 for the period 1990-2000. Note however that these results should be considered with caution, as all estimates are not statistically significant for the subsamples considered.

4.5 Form of government

For given council composition, there is an ecdotal evidence that the form of government may play a role as well in the enfranchisement of minorities. The two main forms, mayor-council and councilmanager, differ with respect to the role of the mayor as the pivot of the executive body (stronger in the first instance). Our model is not centered on the role of form of government³⁹ but in this section we briefly review empirical evidence which may be per se relevant. In cities where the white voters hold a solid majority and are almost sure of electing a white mayor, they may prefer a strong mayor form of government. On the other hand, in cities with a closer fifty-fifty split, the white constitutional writers may prefer a council-manager form of government to avoid the risk of ending with a black strong mayor. The following quote from an editorial from a newspaper targeted to Hispanics in San Diego (La Prensa, April 24, 2004) is an example of how the form of government may enter the picture. In discussing proposed changes in the charter of the city of San Diego, the editorial concludes that "For Hispanics having a strong mayor form of government does not bode.... well for this community. Putting so much power into one person's hands....translates into control by Republican right wings. Regardless of the changing demographics, i.e. the continual growth of the Hispanic, Asian, Filipino, black community political representation in the city of San Diego will be held by a diminishing number of white ...citizens." A relatively weak council hardly exercises any effective check on executive powers. A powerful council plays exactly the opposite role in council-manager structures.

We consider two "form of government" indexes increasing in the power of the executive. The first index, indicated as FOG, takes the value of 1 for mayor-council, 0 for council-manager and -1 for Commission or Representative Town Meeting or Town Meeting. The second index, indicated as SIND, is constructed as increasing function of provisions strengthening the executive (like mayor-council and veto power) and decreasing in provisions weakening the executive (for example, recall).⁴⁰ A strong mayor could be preferred by the charter writers as long as their position as majority of the city is strong, but a strong mayor is relatively riskier whenever minorities are large

³⁹See our discussion in the extensions of the basic model.

⁴⁰The mayor-council form of government consists of an at-large elected mayor (the executive branch) and a legislative branch, the council of councilmen (or aldermen), elected by ward, at-large, or a mix of both rules. The mayor acts as chief executive officer of the city. Mayor's powers vis-a-vis the council vary within this typology of government. Typically we have two variants, weak-mayor and strong-mayor. The council-manager form of government consists of a legislative branch, the council, which selects and supervises a professional administrator, the city manager. The manager is in charge of the implementation of the policy and day-to-day municipal administration and can be removed or fired by the council at will.

enough. At that point the more collegial council-manager form could be employed (given that whites could still be able to seat in the council). Therefore, to be congruent with our results on electoral rule, we would expect a positive coefficient on the size of the minority and perhaps a negative quadratic term in a regression where form of government is the dependent variable. Table 8 is organized as Table 1, a two-way panel model, while Table 9 mirrors Table 3, a dynamic panel model. Both Tables employ FOG as dependent variable. Table 10 instead presents the static panel model for $SIND^{41}$.

These Tables suggest a blurred picture. The coefficient of size of the minority in the post-1967 sample has the expected sign only in a limited subset of regressions in Table 10, but never in Tables 8 and 9. Moreover, the coefficient on ethnic fractionalization is not statistically significant in most specifications for the South (or it is at 10 percent, but with the wrong sign). This same coefficient is insignificant (in fact very close to zero and switching sign) in the pre-1967 sample. The explanation for the wrong signs has often to do with the correlation between form of government and electoral rule (council-manager forms tend to employ at-large elections). Surely, further analysis of this issue (especially the institutional complementarity between form of government and electoral rule) is necessary, but on a first approximation it would appear that electoral rules more than forms of government respond to the racial composition of a city. Not surprisingly perhaps: electoral rules are the intuitive first line of defense against extensions of the democratic franchise.

5 Conclusions

Electoral rules are endogenous and evolve relatively quickly in response to changing underlying conditions. Minority representation depends on the ability of a majority bloc to adapt institutions to changing conditions and guaranteeing its supremacy. The experience of voting rights and electoral institutions in US cities, particularly in the South, is illuminating. Before the Voting Rights Act of 1965, racial minorities were essentially disenfranchised in the US South. Therefore, the type of electoral institutions were irrelevant in determining the level of control of the white majority: a level of control that was almost absolute. The Voting Rights Act allowed racial minorities to enter into the political arena. The white majorities reacted, within the legal boundaries of the Voting Rights Act, by changing electoral rules as to minimize expected minority influence.

This evidence suggests how institutions (in this case electoral rules) evolve even rather quickly in response to changes in the environment and raises questions about empirical evidence that holds electoral institutions as exogenous.

⁴¹The lack of pre-1980 observations for most components of SIND limit our analysis to the simple static model.

6 Appendix: Proofs of Propositions

Proof of Proposition 1

Part (a) is straightforward. For part (b) consider that:

$$L_W^{AL} = 0 < L_W^{SD} \text{ if } \pi \in \left(\frac{1}{3} - \frac{\overline{\alpha}}{6}, \frac{1}{2} - \frac{\overline{\alpha}}{6}\right);$$

and L_W^{AL} and L_W^{SD} are both linear increasing in π for $\pi \in (\frac{1}{2} - \frac{\overline{\alpha}}{6}, \frac{1}{3})$. At $\pi = \frac{1}{3}$, we may have two cases. Case 1: it holds that

$$L_W^{AL} = \left(1 - \frac{1}{\alpha}\right)\Delta > L_W^{SD} = \delta$$

and hence the existence of a unique cut-off $\hat{\pi} \in \left(\frac{1}{2} - \frac{\overline{\alpha}}{6}, \frac{1}{3}\right)$ with the desired properties. Case 2:

$$\Delta\left(1-\frac{1}{\overline{\alpha}}\right) \leq \delta \text{ and } \Delta > \delta.$$

For $\pi \in (\frac{1}{3}, \frac{1}{2})$ the loss L_W^{AL} is linear increasing in π and L_W^{SD} is constant at δ . Hence the existence of a unique cut-off $\hat{\pi} \in (\frac{1}{3}, \frac{1}{2})$ in this case. Finally, to establish part (c) consider that for any π between 0 and $\frac{1}{2}$, we have:

$$L_W^{SD} \ge L_W^{AL}$$

since here $\Delta = \delta$ and

$$\left(1 - \frac{2}{\overline{\alpha}}(1 - 3\pi)^{+}\right)^{+} \ge \left(1 - \frac{3}{\overline{\alpha}}(1 - 2\pi)\right)^{+}.$$
 (8)

At $\pi = \frac{1}{2}$ (8) holds with equality. This establishes the proposition.

Proof of Proposition 3

Define $N_1/N = n_1$ and $\rho = N_{TOT}/N$. Normalize u(0) = 0. The expected utility of a pure AL is:

$$U_W^{AL} = \Pr(\alpha < X)u(1),$$

where $X(\pi) = N(1 - 2\pi)$.

The probability under a single-member district system of winning type-2 districts $1, 2, ..., N_2$ for W is:

$$\Pr\left(\alpha < \frac{(1 - 2\pi N/N_2)}{f}\right)$$

With constant $f = 1/N_2$ indicate $Y(\pi) = \frac{(1-2\pi N/N_2)^+}{f} = (N_2 - 2\pi N)^+$. Then the expected utility of pure SD for given π is:

$$U_W^{SD} = \Pr(\alpha > Y)u(n_1) + \Pr(\alpha < Y)u(1).$$

Notice that $X(\pi) > Y(\pi), \forall \pi$.

Consider the value of π^* at which the expected share of seats won by W is the same under pure AL and pure SD. For any $\pi < \pi^*$, AL is actuarially more favorable than SD. If W is risk averse, the $\hat{\pi}$ at which $U_W^{SD} = U_W^{AL}$ lays in the interval (π_0^{AL}, π^*) , since AL is a riskier electoral rule. A unique point $\hat{\pi}$ always exists as a consequence of Part b) of Proposition 2. It follows that

$$U_W^{SD} = U_W^{AL}$$

$$\Longrightarrow \Pr(\alpha > Y) = \Pr(Y < \alpha < X) \frac{u(1)}{u(n_1)},$$
(9)

where

$$\Pr(\alpha > Y) = 1 - (N_2 - 2\pi N)^+ / \overline{\alpha}$$

 $\Pr(Y < \alpha < X) = N_1 / \overline{\alpha}$

Hence (9) implies that at $\hat{\pi}$:

$$\frac{u(1)}{u(n_1)} = \frac{\overline{\alpha}}{N_1} - \frac{1}{N_1} \left(N_2 - 2\hat{\pi}N \right)^+ < \frac{\overline{\alpha}}{N_1} < \frac{N}{N_1}$$
 (10)

A risk averse W will always accept at least a small amount of risk that is actuarially favorable. Therefore, at $\hat{\pi}$ W will prefer a mixed system to a pure SD rule.

To see this, define the number of SD councilmen per district $\underline{\rho}$ and consider the problem of W for $\pi = \hat{\pi}$:

$$\max_{\underline{\rho}} \left\{ U_W^{MX}(\underline{\rho}) \right\}$$

subject to $0 \le \underline{\rho} \le \rho$.

The expected utility of a mixed system MX for given π is:

$$U_W^{MX} = \Pr(\alpha > X)u(\underline{\rho}n_1/\rho) + \Pr(Y < \alpha < X)u\left((\underline{\rho}n_1 + \rho - \underline{\rho})/\rho\right)$$

$$+ \Pr(\alpha < Y)u(1)$$
(11)

By using the expression in (11) and allowing $\underline{\rho}$ to take continuous values the FOC for the problem is:

$$\Phi(\underline{\rho}) = \frac{1}{\rho} \left[n_1 \Pr(\alpha > X) u'(\underline{\rho} n_1/\rho) - (1 - n_1) \Pr(Y < \alpha < X) u'(\underline{(\rho} n_1 + \rho - \underline{\rho})/\rho) \right].$$

Consider $\Phi(\rho)$ at $\pi = \hat{\pi}$:

$$\Phi(\underline{\rho}) = \frac{\Pr(Y < \alpha < X)}{\rho N} * \left[N_1 \left(\frac{u(1)}{u(n_1)} - 1 \right) u'(\underline{\rho} n_1/\rho) - N_2 u' \left(\left(\underline{\rho} n_1 + \rho - \underline{\rho} \right) / \rho \right) \right].$$
(12)

where we use the fact that $\Pr(\alpha > X) = \Pr(\alpha > Y) - \Pr(Y < \alpha < X)$ and condition (9). We are interested in evaluating (12) at $\underline{\rho} = \rho$:

$$\Phi(\underline{\rho} = \rho) = \frac{\Pr(Y < \alpha < X)}{\rho N} u'(n_1) \left[N_1 \left(\frac{u(1)}{u(n_1)} - 1 \right) - N_2 \right]. \tag{13}$$

By replacing in (13) the expression in (10) we can see that the FOC is strictly negative at $\underline{\rho} = \rho$. This is because the element in brackets in (13) is strictly negative by (10):

$$N_1 \frac{u(1)}{u(n_1)} - N < 0.$$

This excludes that W will choose a pure SD system. Since at $\hat{\pi}$ U_W^{SD} is not the optimum and $U_W^{SD} = U_W^{AL}$, then a pure AL rule cannot be an optimum either. This implies W will choose a mixed system with $\underline{\rho} \neq 0$, $\underline{\rho} \neq \rho$. Finally, by continuity in a neighborhood (π_3, π_4) of $\hat{\pi}$ the same must hold.

This establishes the proposition.

Notes: Standard errors in brackets below coefficients. * significant at 10%; ** significant at 5%; *** significant at 1%. Standard errors are clustered at the city level. All regressions include year fixed effects. Term limit of mayor is computed as 1-max no. terms/8 if term limits are present, 0 otherwise. The executive index is computed as the sum of 1 if the system is mayor-council, 1 if the mayor has veto power, and length of term for the mayor divided by 7, and subtracting term limit, - 1 for the presence of recall, initiative or popular referendum.
