The Prediction Project

The Past and Present of the Future

Uncertainty about Uncertainty

by Alyssa A. Goodman, May 18, 2020

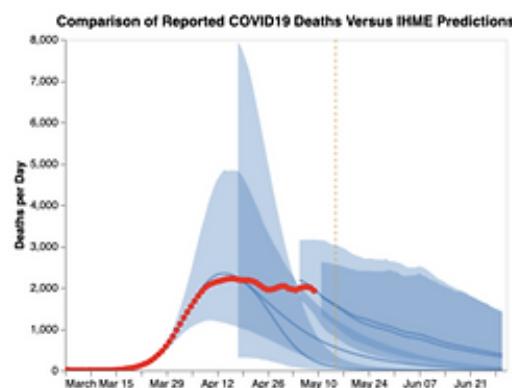

This essay accompanies the release of an online [tool for visualization of IHME COVID-19 forecasts](#) evolution over time and a [community discussion](#) of visualizations created with the tool.

Uncertainty about the future has motivated predictions for millennia. Sometimes, we're just curious—but other times, we really need to know. As the present pandemic evolves, our urgent societal need to plan has motivated many scientists to predict the spread and effects of the novel coronavirus.

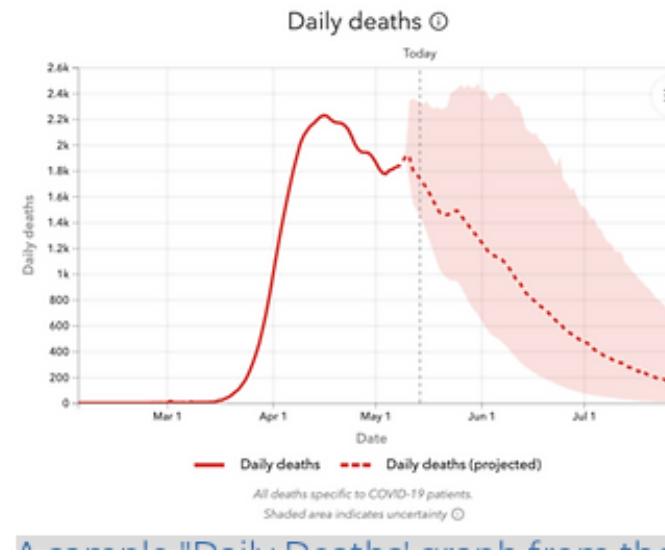

BACKGROUND: TWO BROAD CLASSES OF MODELS

Amongst the many predictions being used by governments to guide policy are two broad classes: infectious disease models based on an understanding of how contagion spreads; and more mechanism-agnostic statistical models informed primarily by data about prior outcomes. To the uninitiated, these approaches, both of which rely on statistical modeling, may sound the same—but they are not.

Models of infectious disease take into account, with varying levels of complexity: how many, and importantly why, people are susceptible, infected, immune, or have succumbed to a virus at any given point in time and space. The mathematics of these models moves people between groups called "Susceptible," "Exposed," "Infected," and "Removed," and so are often called "SEIR" models. At the philosophical other end of the modeling spectrum, what we call "**mechanism-agnostic**" approaches use information about cases, testing, hospital admissions, and deaths, to create algorithms that forecast what will happen under various combinations of conditions, given what's happened under similar conditions in the past. Purely mechanism-agnostic approaches do not factor in medically-informed information about how an infectious disease spreads.

[Click here open the interactive site and explore the visualizations on your own.](#)

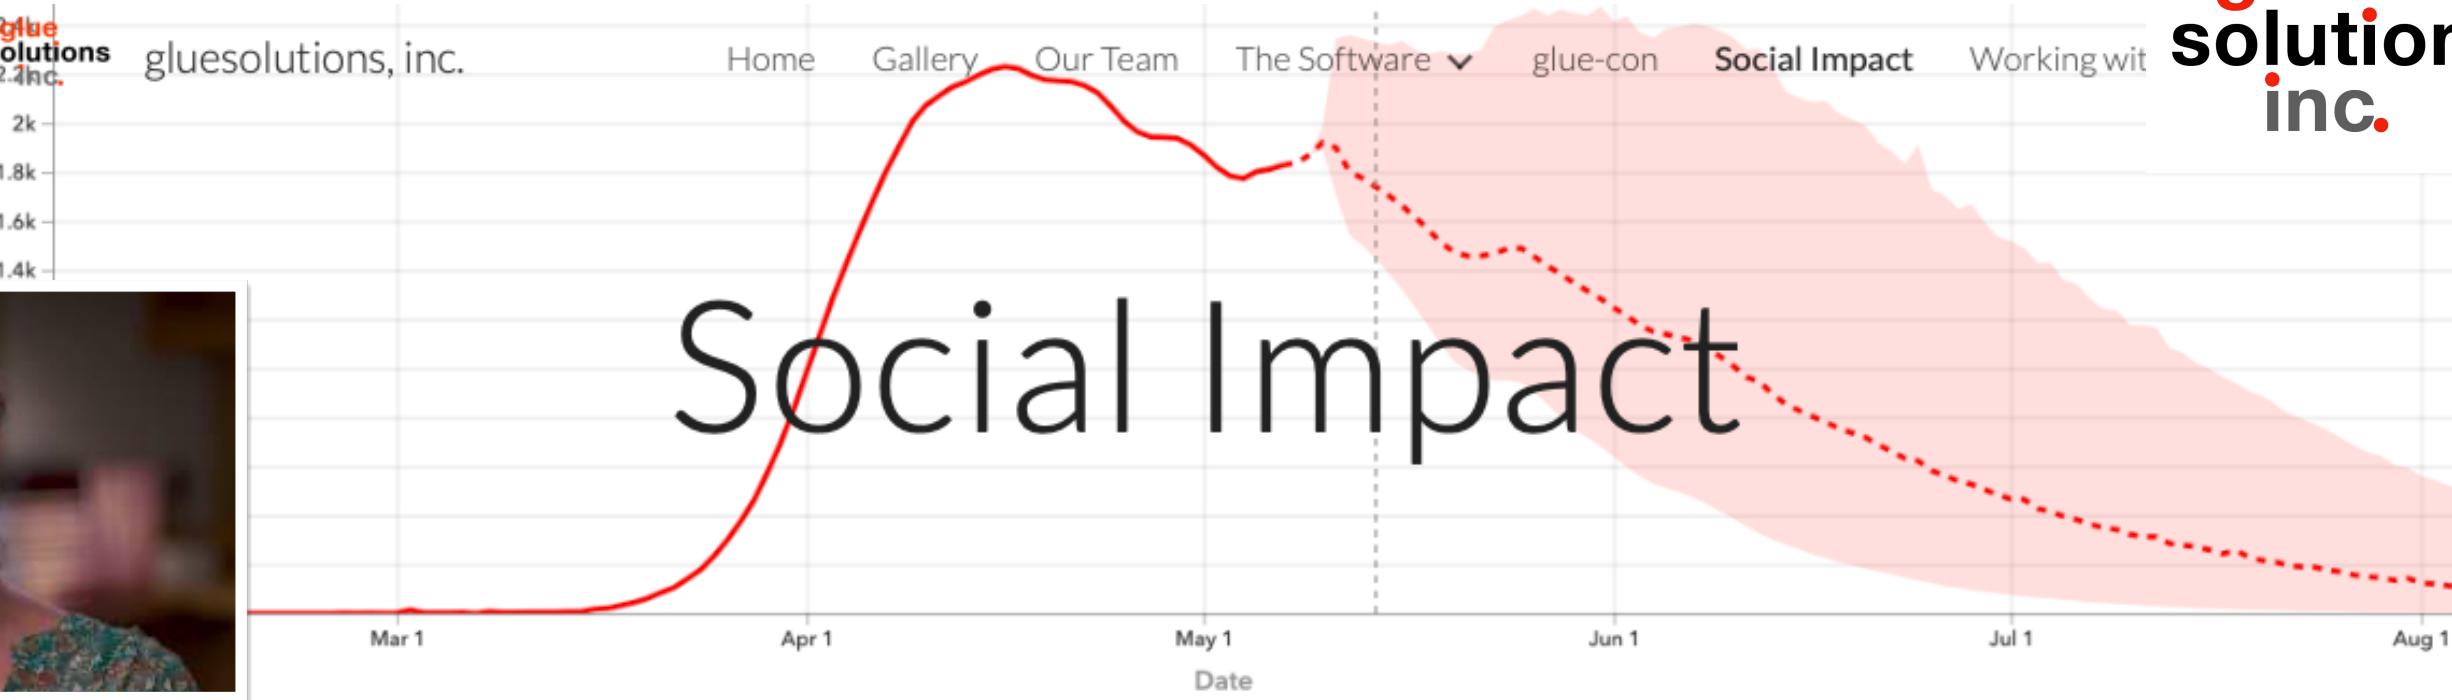

At the moment, there are scores of unrefereed articles in scholarly journals, and hundreds of media articles about predictions from infectious disease models, mechanism-agnostic approaches, and various hybrids, available to policy makers. What isn't clear, though, is how much faith to put in any of these analyses or forecasts.

For most of the SEIR-style predictions, one sees a range of scenarios offered in journal articles, from a miraculous end to the pandemic due to summer, to a devastating "second wave" to come in the fall of 2020, and waves beyond. Human factors, including both government regulation and compliance with it, are often the most unpredictable

Thanks to Caroline Buckee for inspiring this "extra" slide!

Social Impact

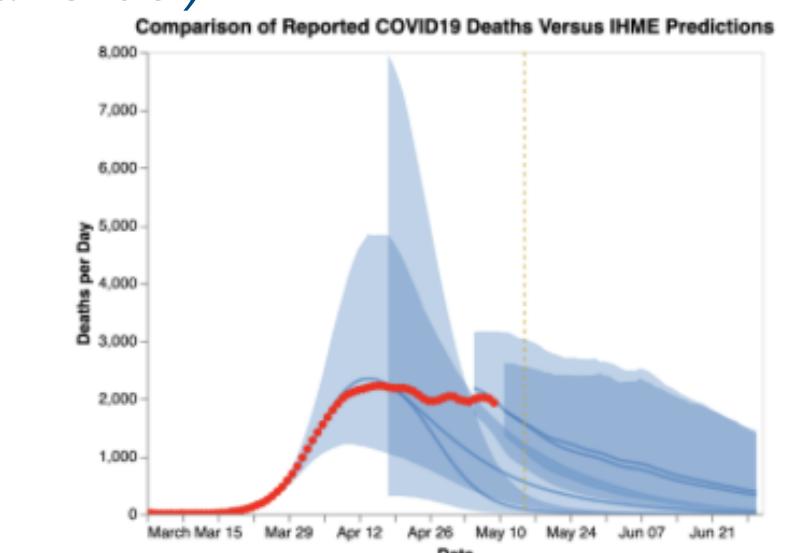

IHME Model Uncertainty, Visualized over Time

The [Institute for Health Metrics and Evaluation \(IHME\)](#) creates, maintains, [updates](#), and publishes an open-source statistical [model](#) of the impact of the COVID-19 pandemic, based on open-data resources. As a public service, [glue solutions, inc.](#) here offers an online tool for visualizing the evolution of the IHME models over time.

The general public has seen many versions of the IHME "Daily Deaths" plots, including in several White House briefings. Our goal here is to offer a look at how the models change—appropriately, in response to new data and information—over time, and how that affects model updates. In a [companion essay online at the Prediction Project site](#), we offer more context on why this evolution is so interesting.

(Banner above shows sample IHME "Daily Deaths" graphic, from 14 May 2020.)

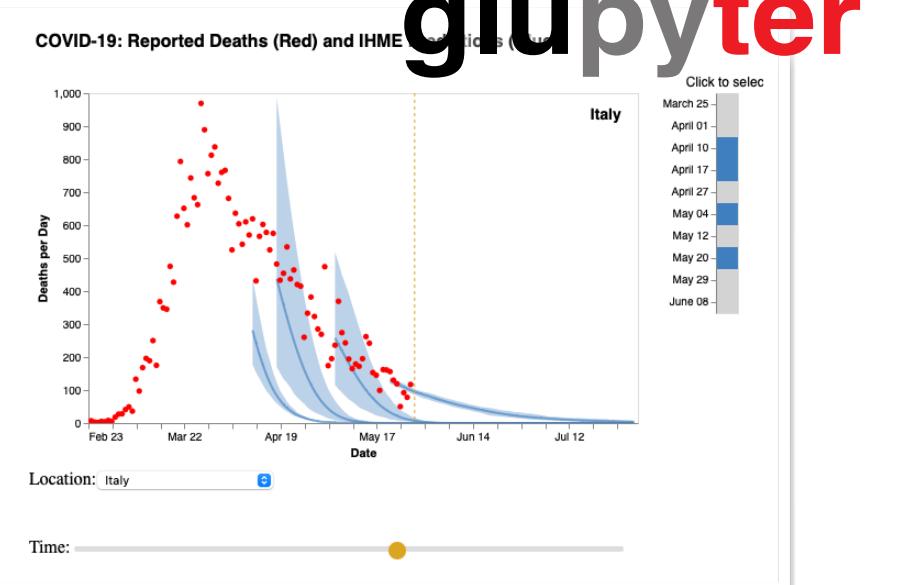

IHME Models over time, for the United States, for 4 representative dates, made with the interactive tools offered below.

What's this tool for? Using the interactive graphics below, you can re-create the display of deaths/day akin to what would have been visible at [IHME's COVID-19 web site](#) on a range of modeling dates, for any region you select. In addition, you can show more than one model (date) at a time, to make comparisons.

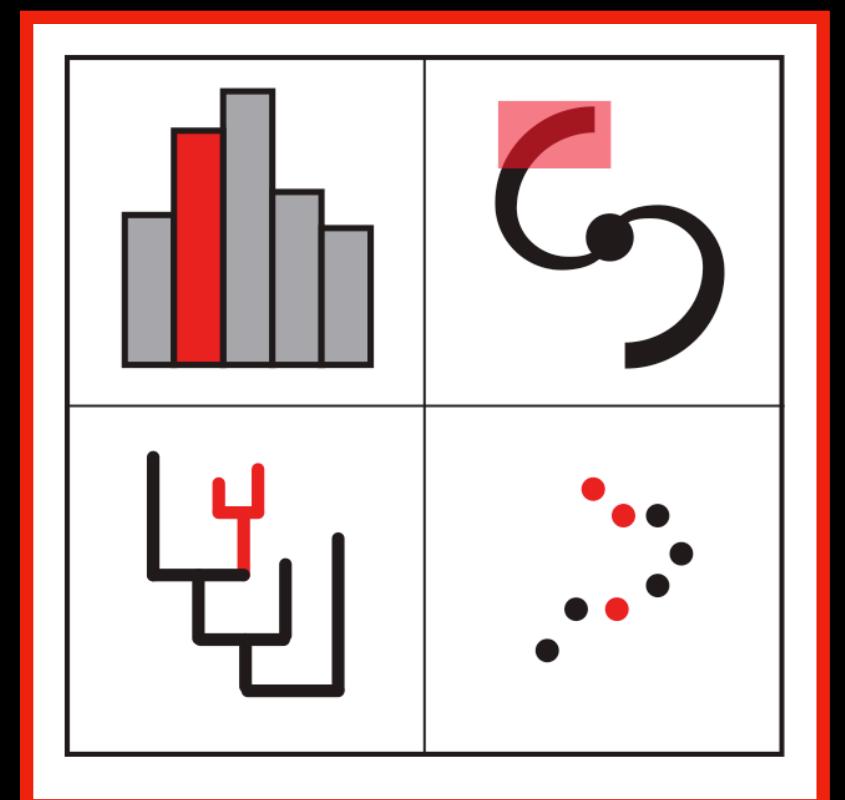

How should I interpret what I see? In each of the panels below: red dots show reported *actual* deaths per day; solid blue lines show forecasts, and light blue shaded regions show uncertainty bands. Those uncertainty bands indicate ranges of possible outcomes, as forecast on the date when the model was made. The ranges should account for 95% of possible outcomes. As one can see by moving the time slider below each graph, the model and its associated uncertainty band change over time. As more and more models are added, regions where shading appears darkest are regions where uncertainty is greatest.

There are four versions of the IHME evolution visualization offered below. They are as follows (with source links):

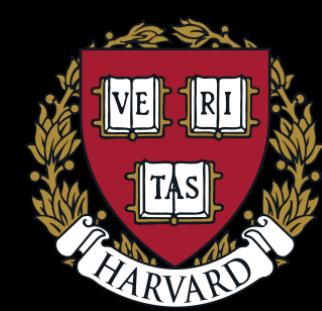

1. For the United States, showing only 4 representative model dates. [\[source\]](#) [\[GitHub\]](#) [\[mobile site\]](#)
2. For the United States, offering a wide range of model dates [\[source\]](#) [\[GitHub\]](#)
3. For the World, showing only 4 representative model dates [\[source\]](#) [\[GitHub\]](#) [\[mobile site\]](#)
4. For the World, offering a wide range of model dates [\[source\]](#) [\[GitHub\]](#)

What is glue?

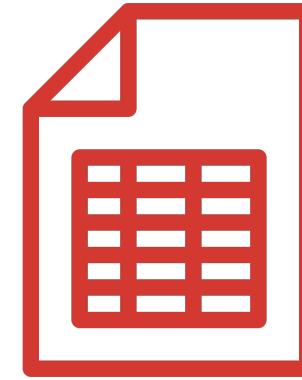

multidimensional data exploration

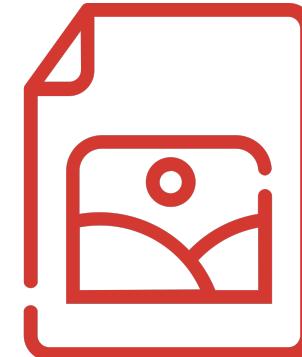

It's not an acronym.

It is open-source software that
glues data,
glues graphs &
glues tools.

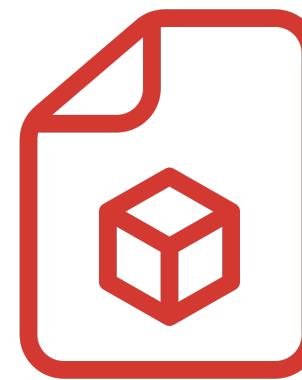

data

numbers (tables, arrays, spreadsheets)

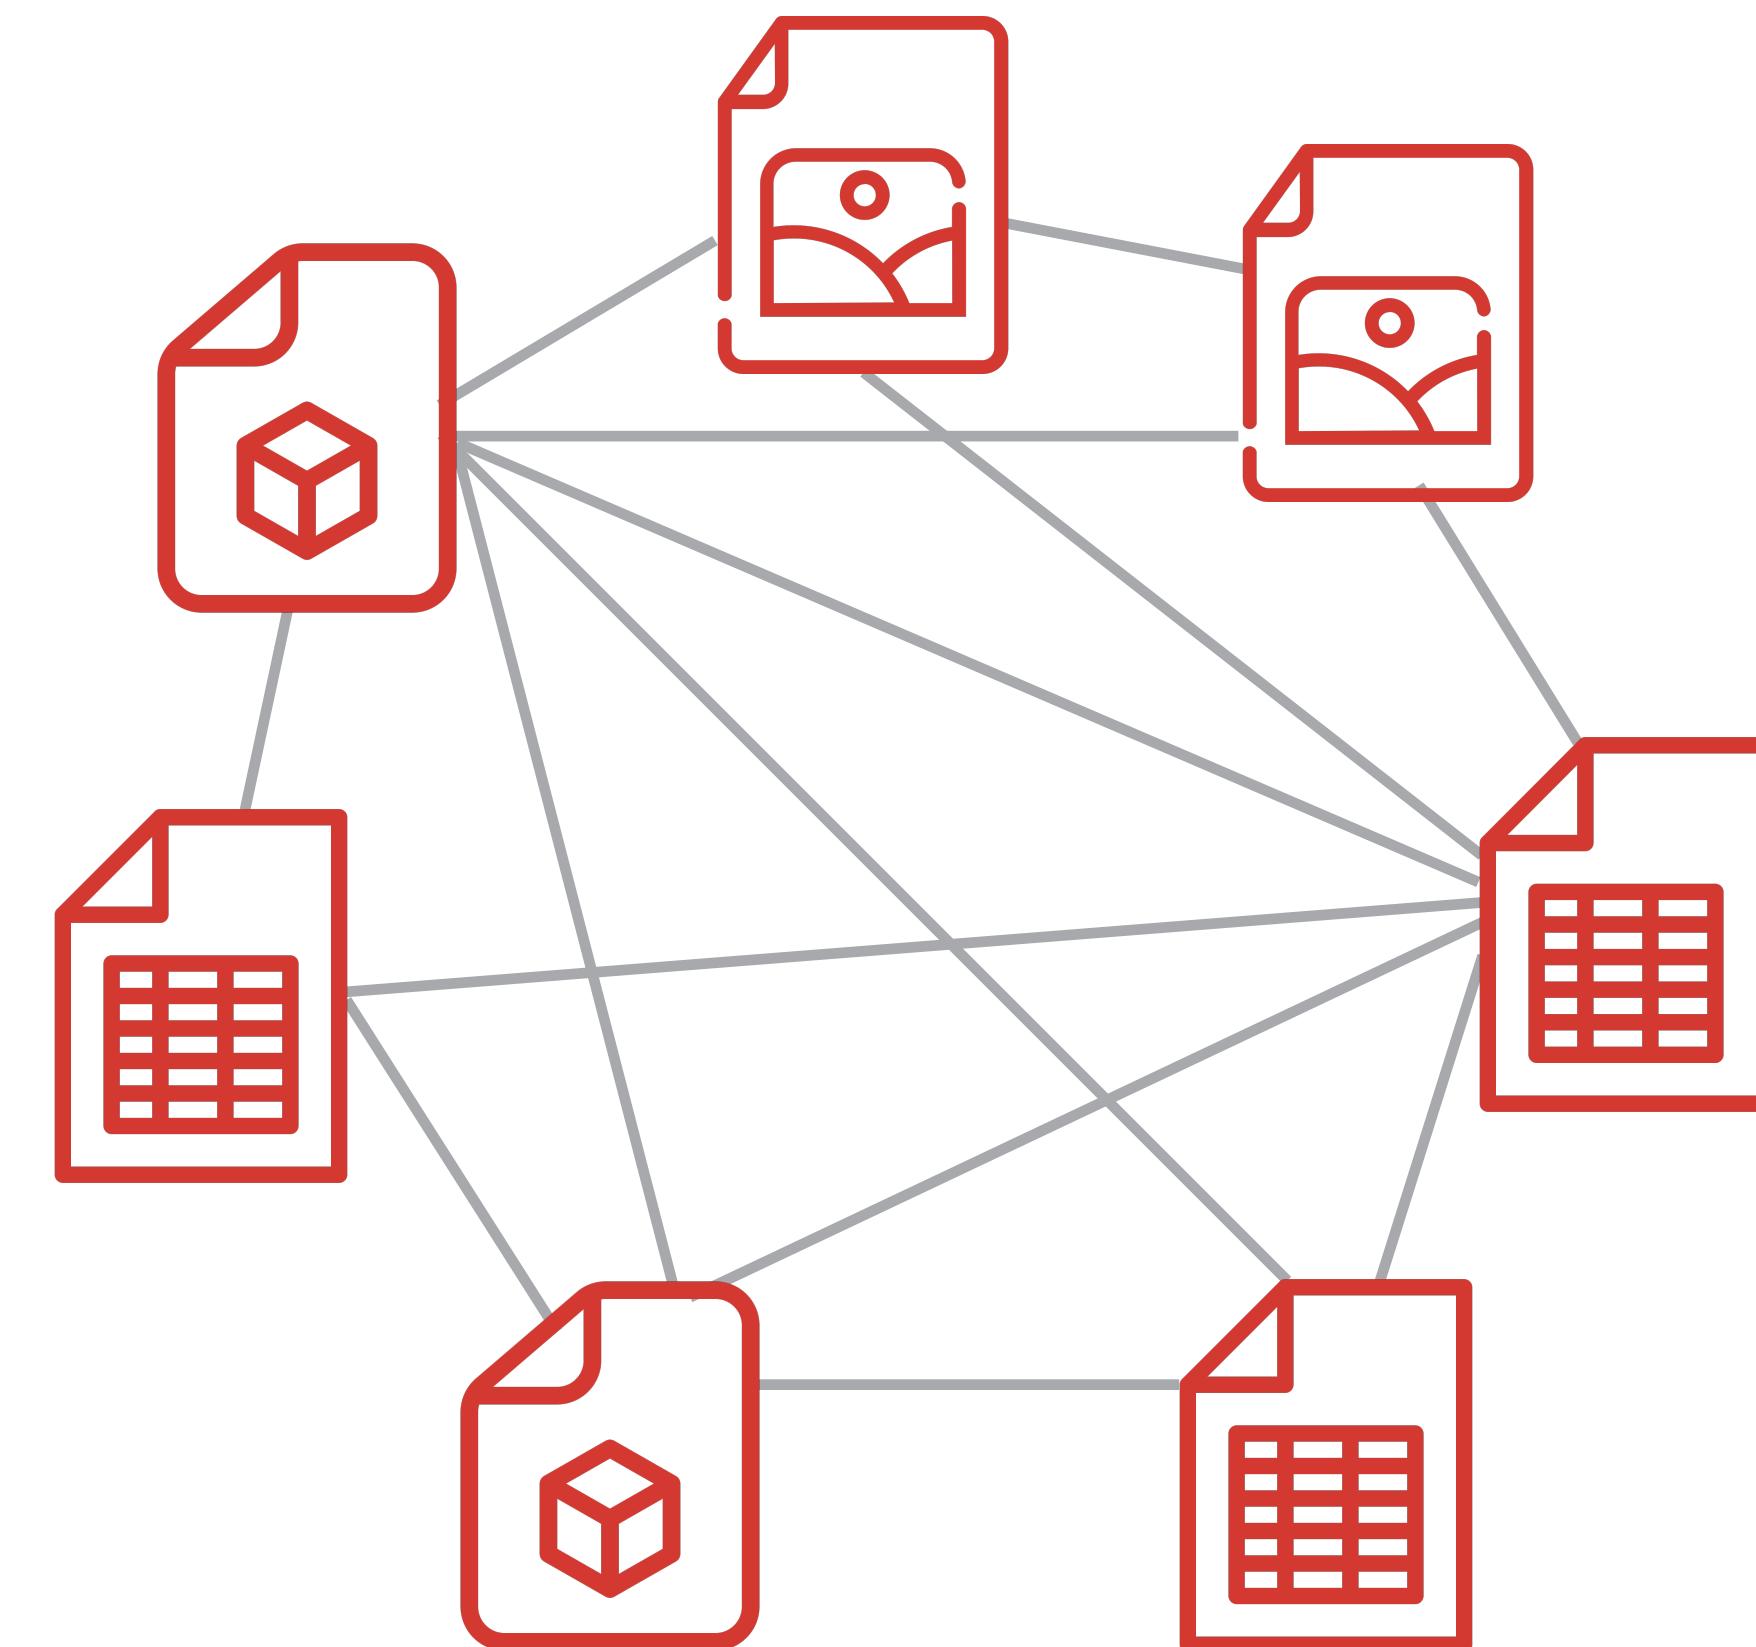

images & maps (FITS, JPEG, GIS and more)

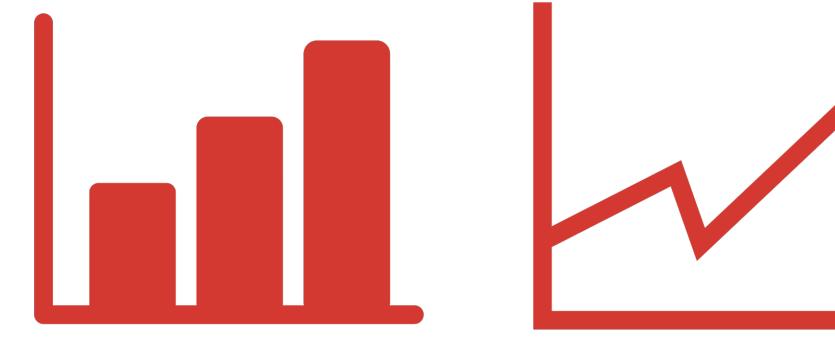

data cubes (3D, 4D, and more)

data files' common attributes are glued

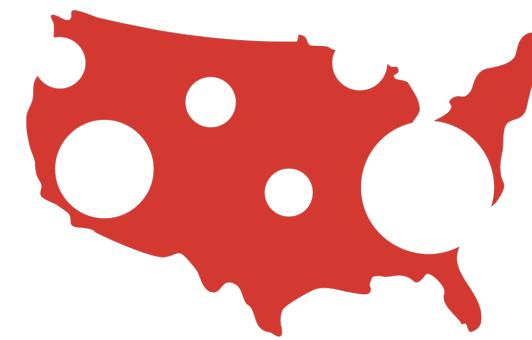

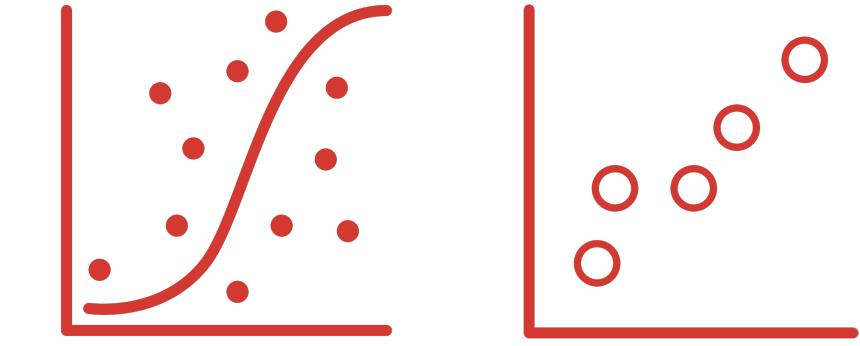

avoiding the need to merge data files

“graphs”

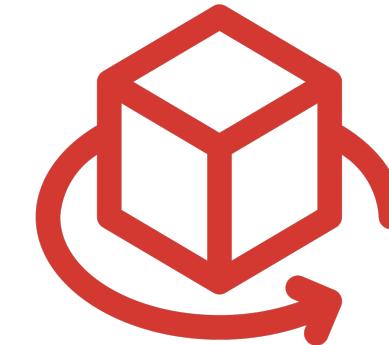

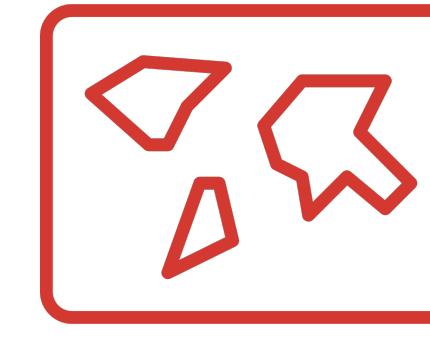

common statistical graphics
(scatterplots, histograms, tables, curves, overlays)

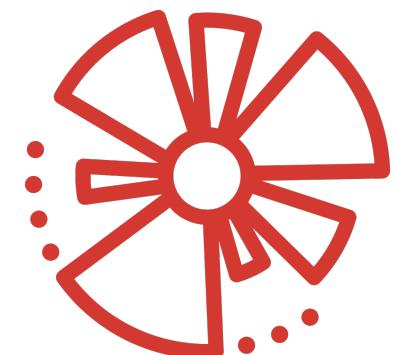

maps & images

(greyscale, color, contours, layer control...)

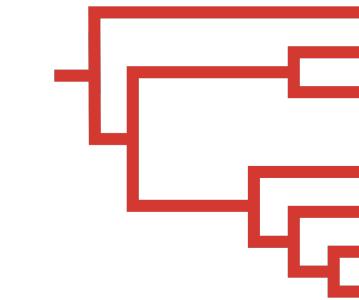

3D displays

(scatter plots, volumetric rendering, sliders...)

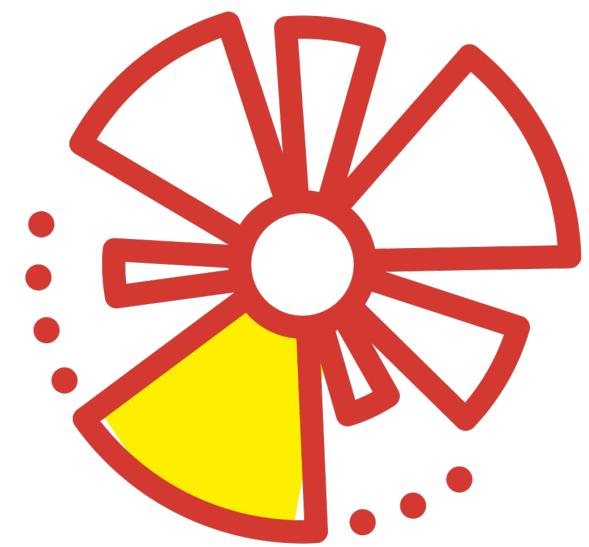

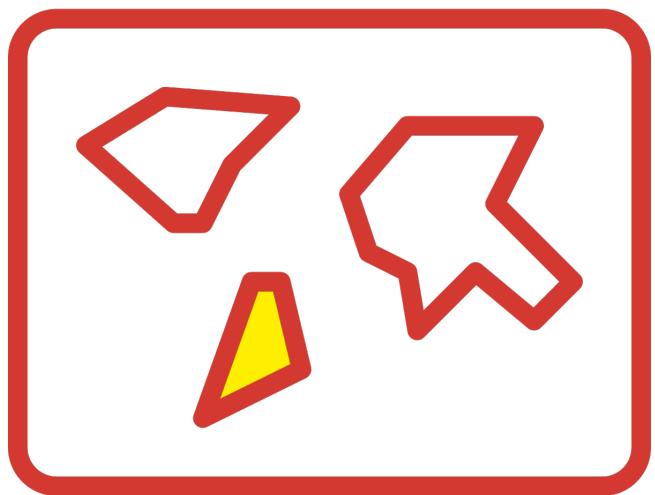

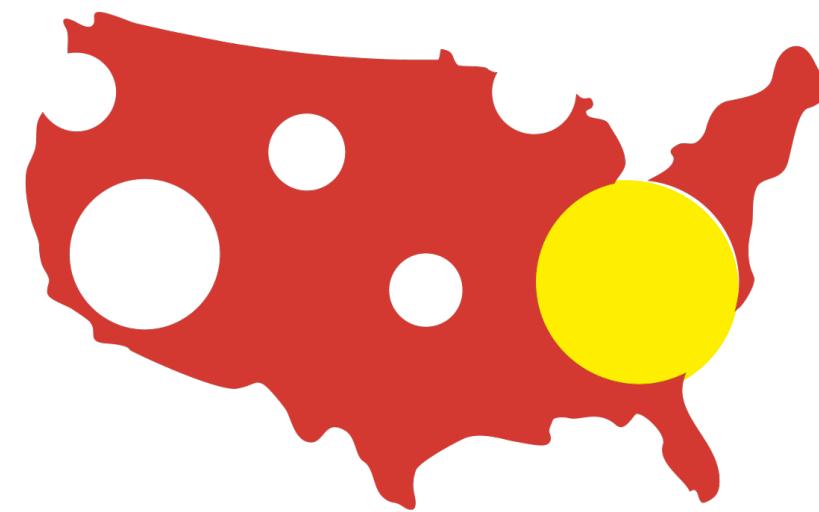

specialized & custom charts

(dendograms, polar plots, + domain-specific options)

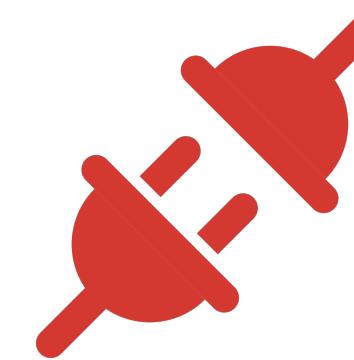

selections propagate across all graphs

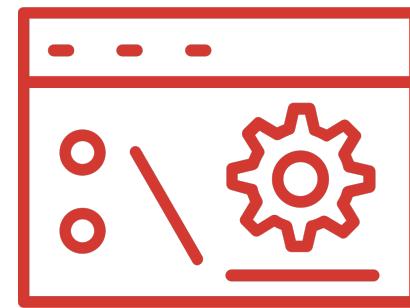

for real-time data exploration & insight

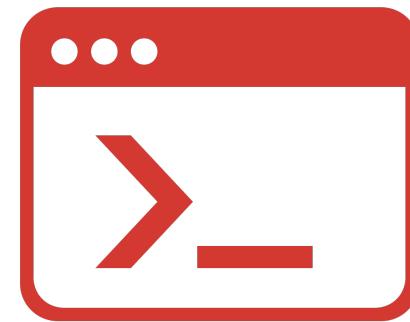

tools

plug-ins (user-defined formats, plots, layouts...)

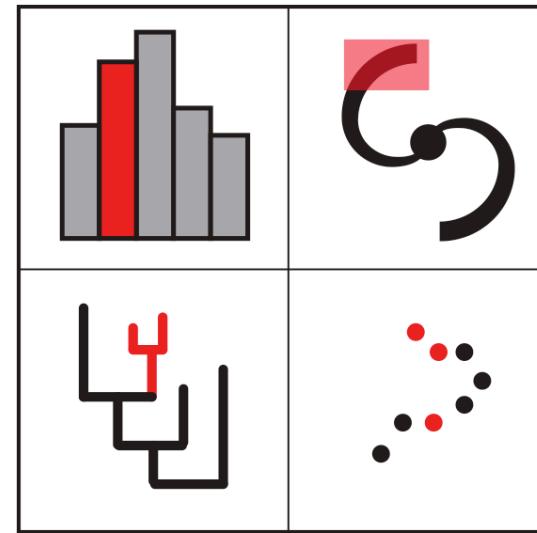

web services (across domains)

command-line (built-in terminal, scriptable)

for easy customization

glue

multidimensional data exploration

**glues data,
glues graphs &
glues tools.**

glueviz.org

BONUS: save, share, or publish what you learn—

save “sessions” to continue where you left off

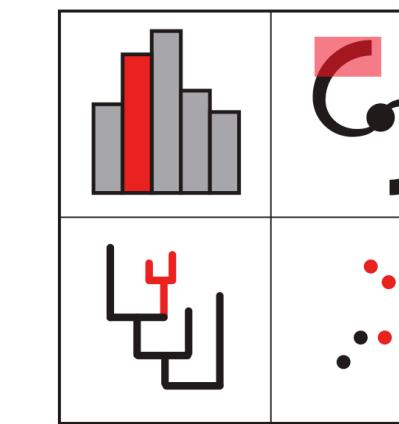

export graphics

use/export to Jupyter environments

export to plot.ly (javascript)

export to augmented reality

glupyter

"glupyter" is a union of [glue](#) and [Jupyter](#) software environments. We think it may well be the future of glue, or "glue-qt" as experts sometimes call the desktop app version of glue. This webpage, hosted openly and freely by [glue solutions, inc.](#), serves as a clearinghouse for current information about open-source glupyter-related projects. Some of these projects are funded by government agencies (notably [NSF](#) and [NASA](#)), others by private foundations (e.g. [The Gordon and Betty Moore Foundation](#)), some as part of corporate collaborations (e.g. [Harvard+Google Data+Climate](#)), and some by open-source consulting work carried out by [glue solutions, inc.](#).

The [glue-jupyter GitHub repository](#) is fully open, and more detail can be found on this [Read the Docs page](#).

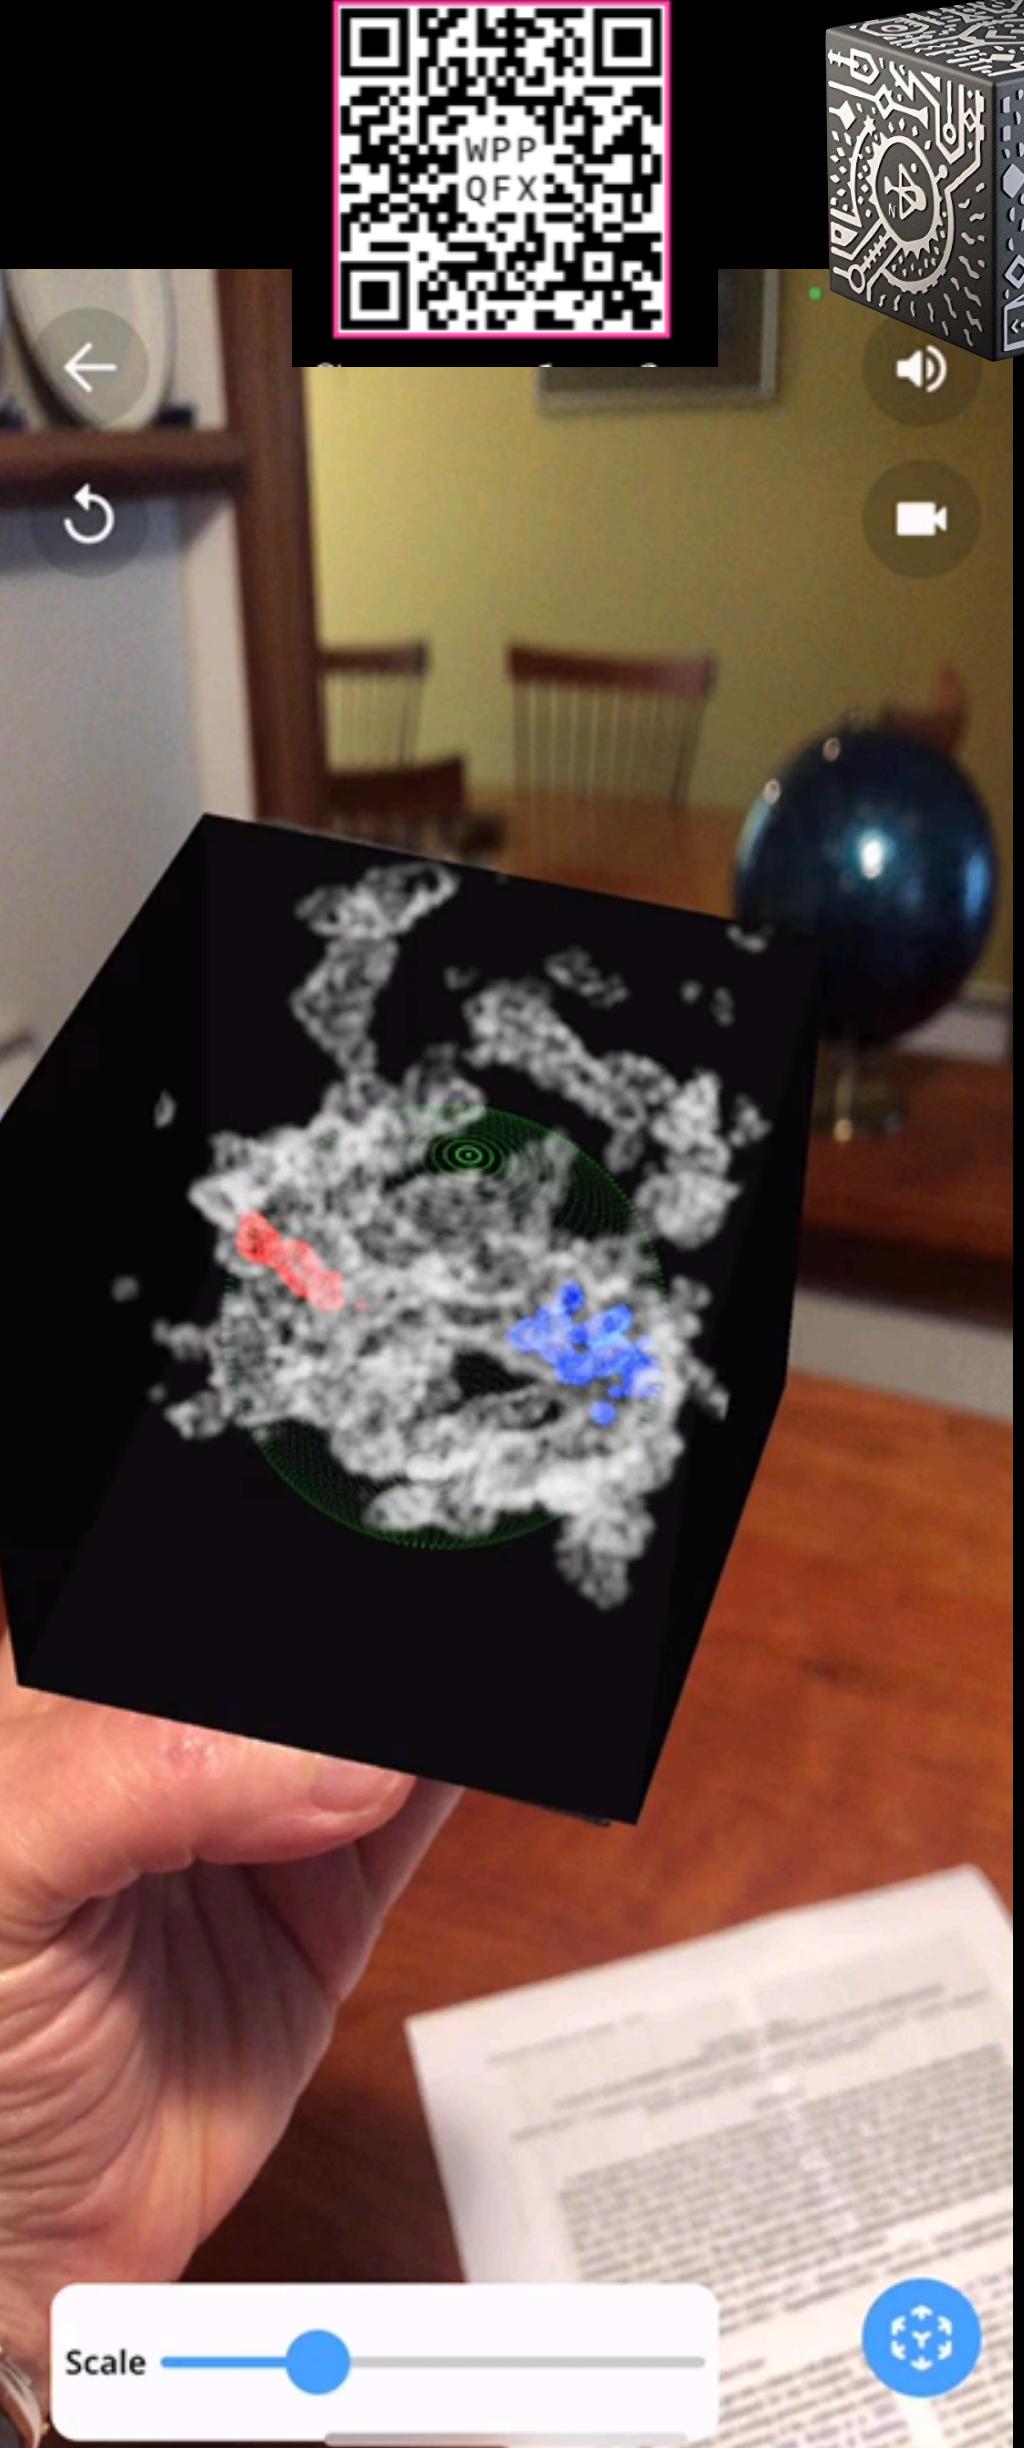

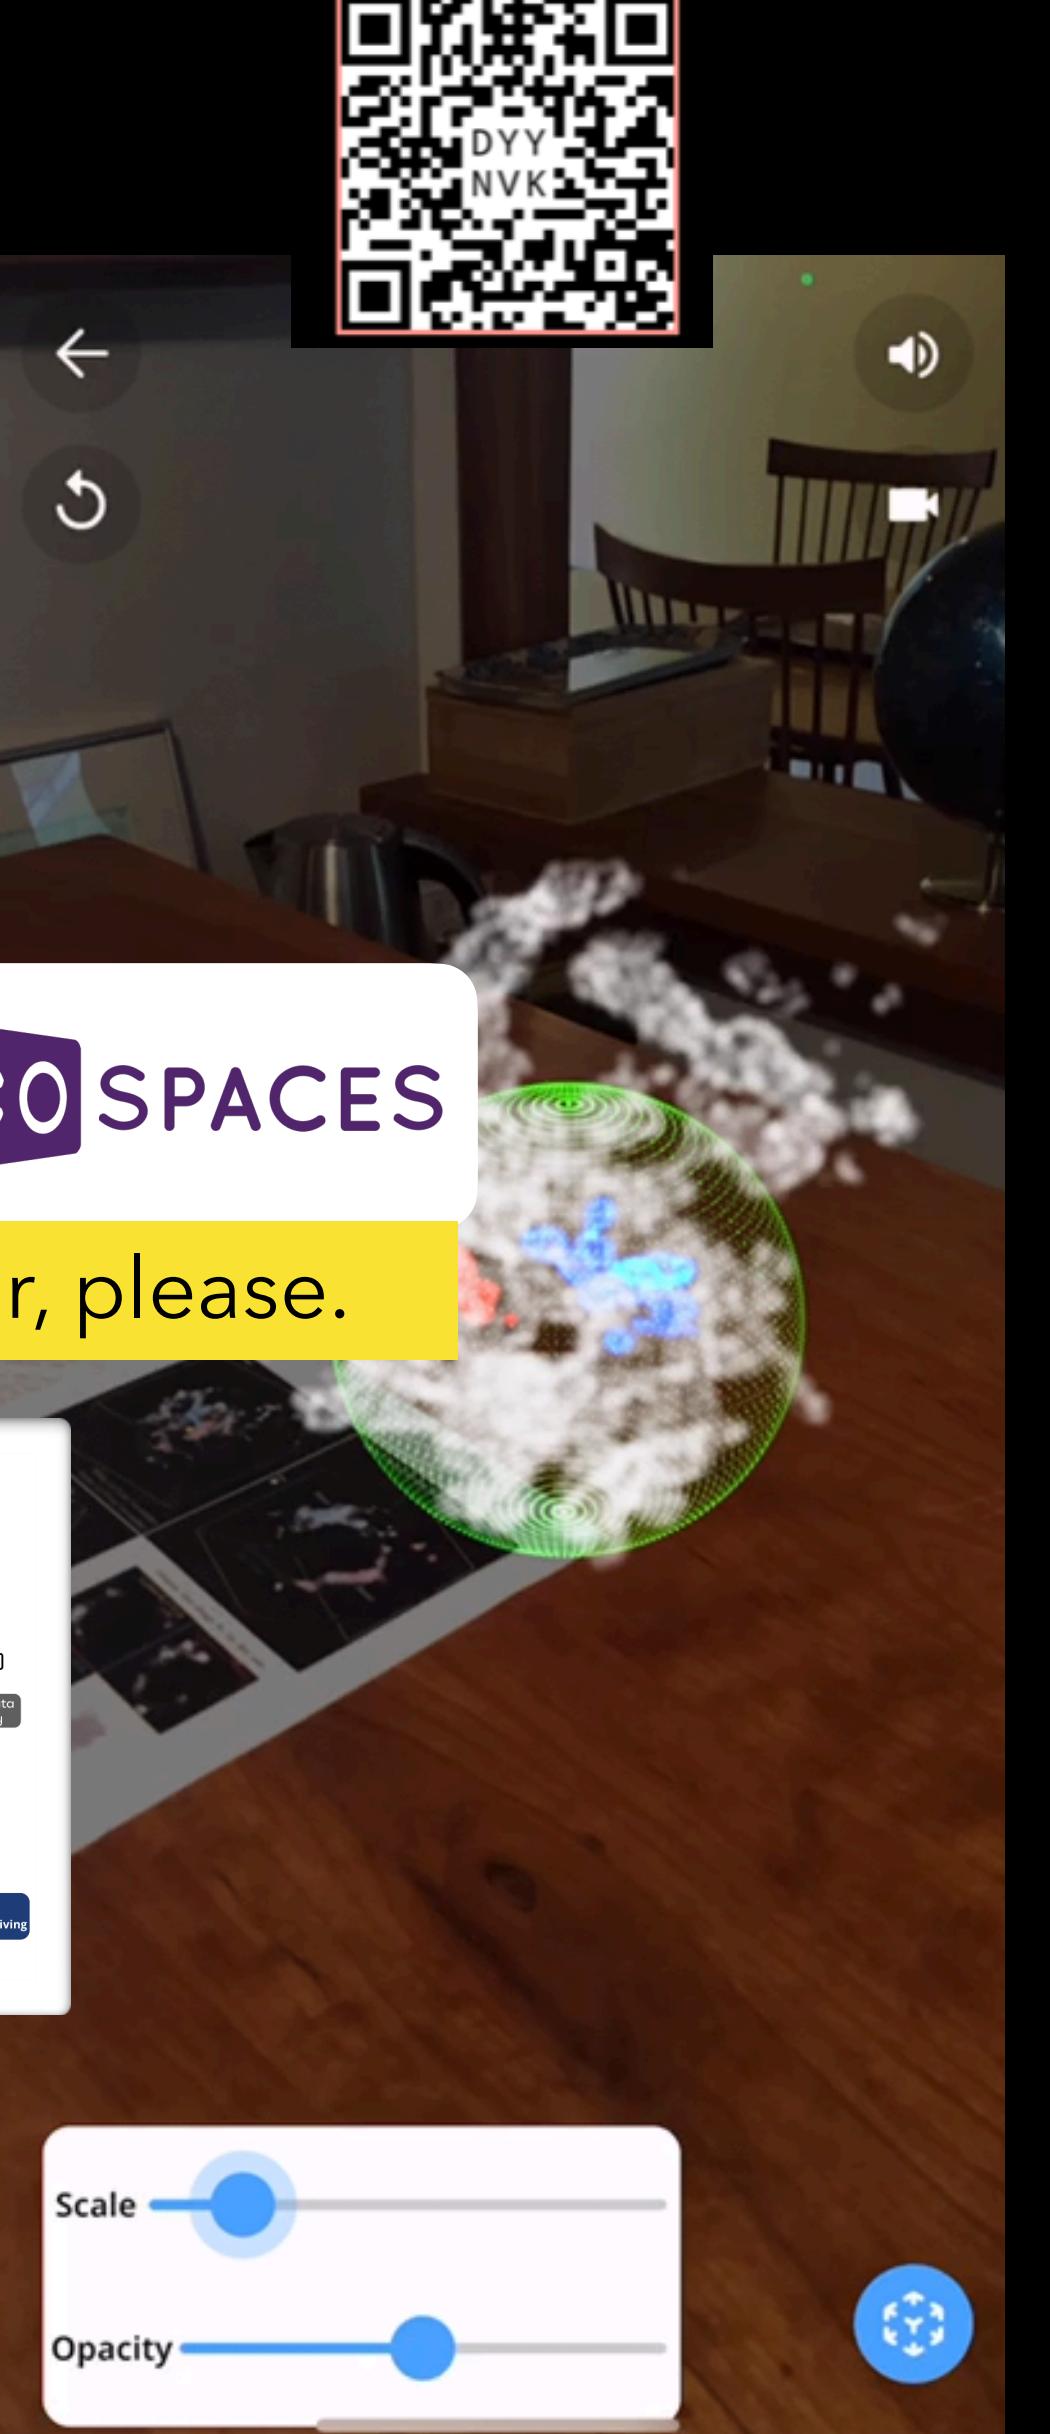

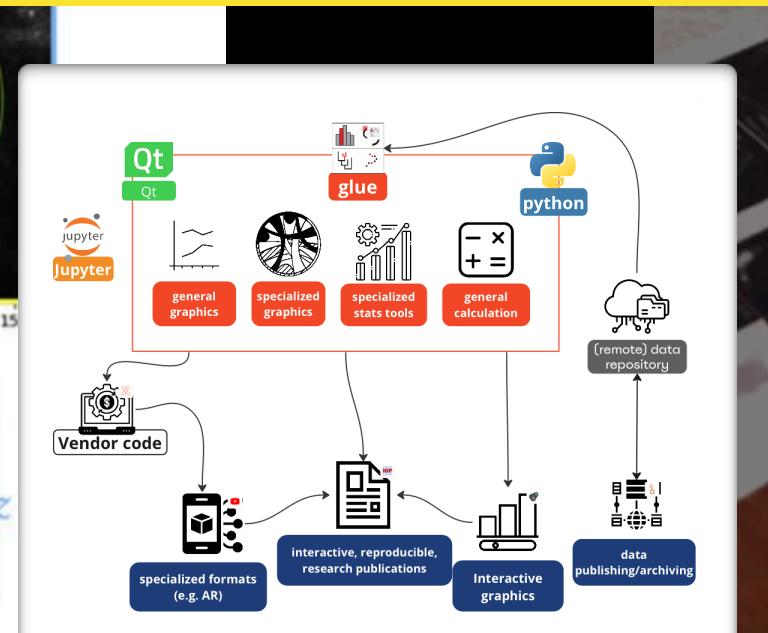

Figure 2. 3D views of the Per-Tau shell (for an interactive version⁸ of this figure click [here](#)⁹; see Figure 5 for more static visualizations). Plotted are density iso-surfaces at levels $n = 5 \text{ cm}^{-3}$ (gray) and $n = 25 \text{ cm}^{-3}$ (color), overlaid with our spherical-shell model, radius $R_s = 78 \text{ pc}$, distance from the Sun $d = 218 \text{ pc}$. The $n = 25 \text{ cm}^{-3}$ surfaces are colored by distance from the Sun (blue-to-red). Top-left panel: view from the Sun (compare with Figure 1). Top-right panel: a side view of the region. Perseus and Taurus and their diffuse envelopes are arranged on two opposing sides of the Per-Tau shell. Bottom-left panel: another side view emphasizing the Tau Ring. The ellipse is the Tau Ring model (Appendix B). Bottom-right panel: 2D density slices along the *xy*, *xz*, *yz* planes. All planes intersect at shell's center. In all panels *xyz* are the Heliocentric Galactic Coordinates.

2. *Tau Ring*: in a sky projection the Tau Ring is seen almost edge-on. The near side of the Tau Ring connects with the main body of Taurus at $d \approx 150 \text{ pc}$, whereas the farthest part extends to $d \approx 220 \text{ pc}$.

3. *The Fictitious Connection*: A filament seems to connect Taurus to Perseus. This connection is only a coincidental projection effect, where in actuality the filament is located at the distance of Taurus, and does not physically connect

MY DATA

Even when data are messy, it is possible to explore relationships between the quantities being graphed. Scientists do this by fitting a model to the data.

Since we saw a trend in the larger class data set, let's start with a trend line. A trend line follows the observed trend in the graphed data.

Click in the Toolbar to activate the drawing tool and try drawing a trend line through your data points.

BACK Click and draw a trend line.

Spatial Transcriptomics

TRANSCRIP

Visualization and analysis of gene expression in tissue sections by spatial transcriptomics

Per Ståhl,^{1,2*} Fredrik Salmén,^{2,*} Sanja Vickovic,^{2,†} Anna Lundmark,^{2,3,†} Juan M. Hernández Navarro,^{1,2} Jens Magnusson,¹ Stefania Giacomello,² Michaela Asp,² Olof Westholm,⁴ Mikael Huss,⁴ Annelie Mollbrink,² Sten Linnarsson,⁵ Simone Codeluppi,^{5,6} Åke Borg,⁷ Fredrik Pontén,⁸ Paul Igor Costea,² Pelin Sahlén,² Jan Mulder,⁹ Olaf Bergmann,¹ Joakim Lundeberg,^{2,‡} Jonas Frisén¹

Analysis of the pattern of proteins or messenger RNAs (mRNAs) in histological tissue sections is a cornerstone in biomedical research and diagnostics. This typically involves the visualization of a few proteins or expressed genes at a time. We have devised a strategy, which we call “spatial transcriptomics,” that allows visualization and quantitative analysis of the transcriptome with spatial resolution in individual tissue sections. By positioning histological sections on arrayed reverse transcription primers with unique positional barcodes, we demonstrate high-quality RNA-sequencing data with maintained two-dimensional positional information from the mouse brain and human breast cancer. Spatial transcriptomics provides quantitative gene expression data and visualization of the distribution of mRNAs within tissue sections and enables novel types of bioinformatics analyses, valuable in research and diagnostics.

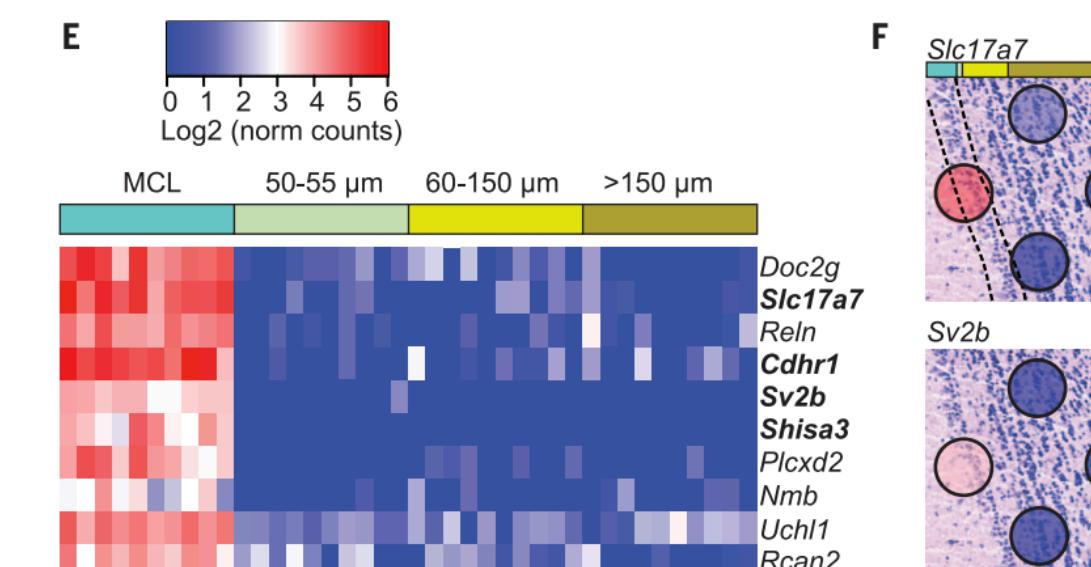

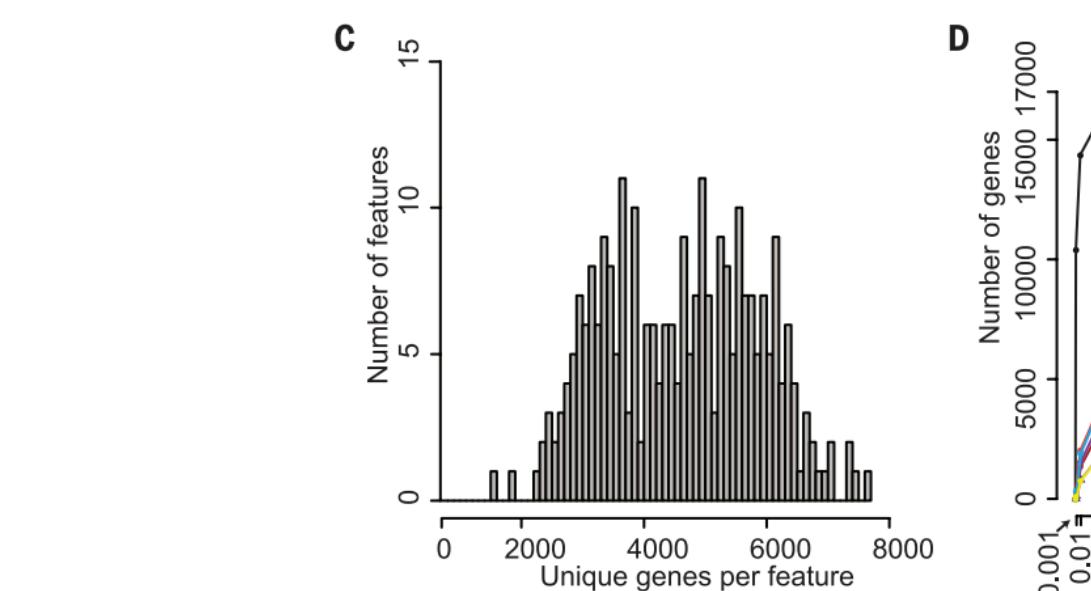

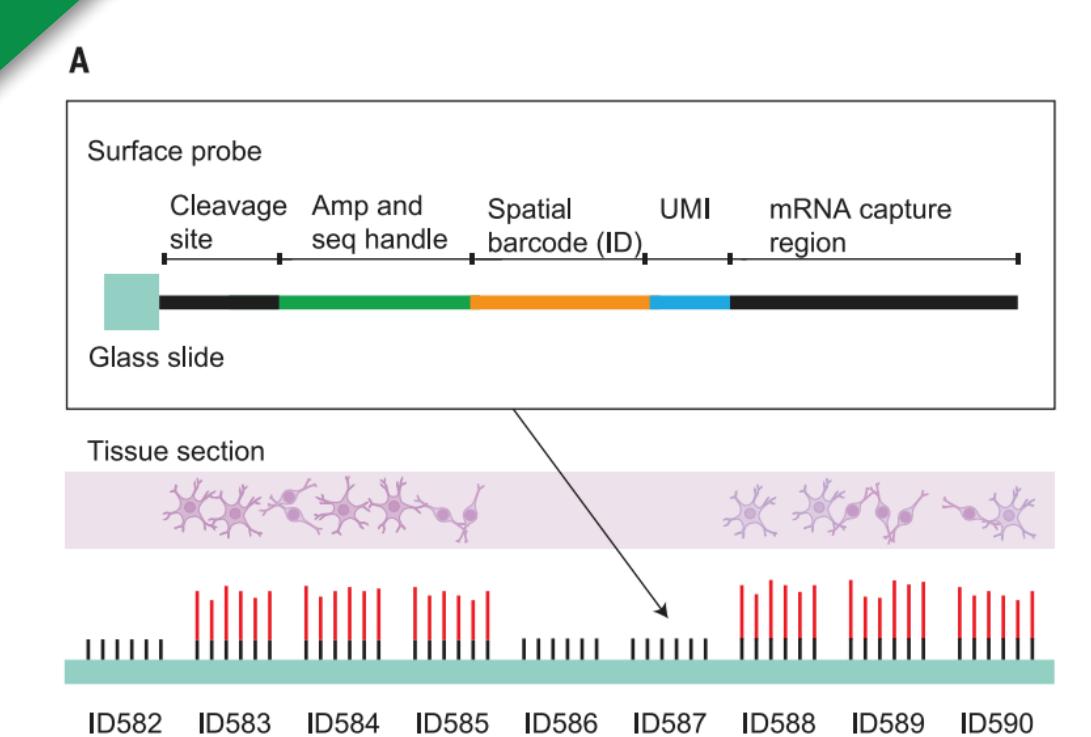

Fig. 2. Spatially resolved gene expression. (A) Each array feature contains unique DNA-barcoded probes containing a cleavage site, a T7 amplification and sequencing handle, a spatial barcode, a unique molecular identifier (UMI), and an oligo(dT) VN-capture region, where V is anything but T and where N is any nucleotide. cDNA (red) is generated from captured mRNA by reverse transcription. (B) Visualization of the expression of three genes by spatial transcriptomics (top) and in situ hybridization (bottom). *Penk* and *Kctd12* in situ images are from the Allen Institute. Cutoff normalized counts, *Penk*, 8; *Doc2g*,

13; and *Kctd12*, 19. (C) Distribution of unique genes per feature under the tissue. (D) Number of genes detected for different layers and entire tissue over sequencing depth. (E) Lateral diffusion of transcripts from genes enriched in MCL. The genes are expressed in MCL features but are not separable from the background in features adjacent to the MCL. (F) Spatial expression and in situ hybridization of four genes in (E). The leftmost feature overlaps the MCL, and the three rightmost features are situated in the GCL. The colored bar depicts the distances from feature center in (E).

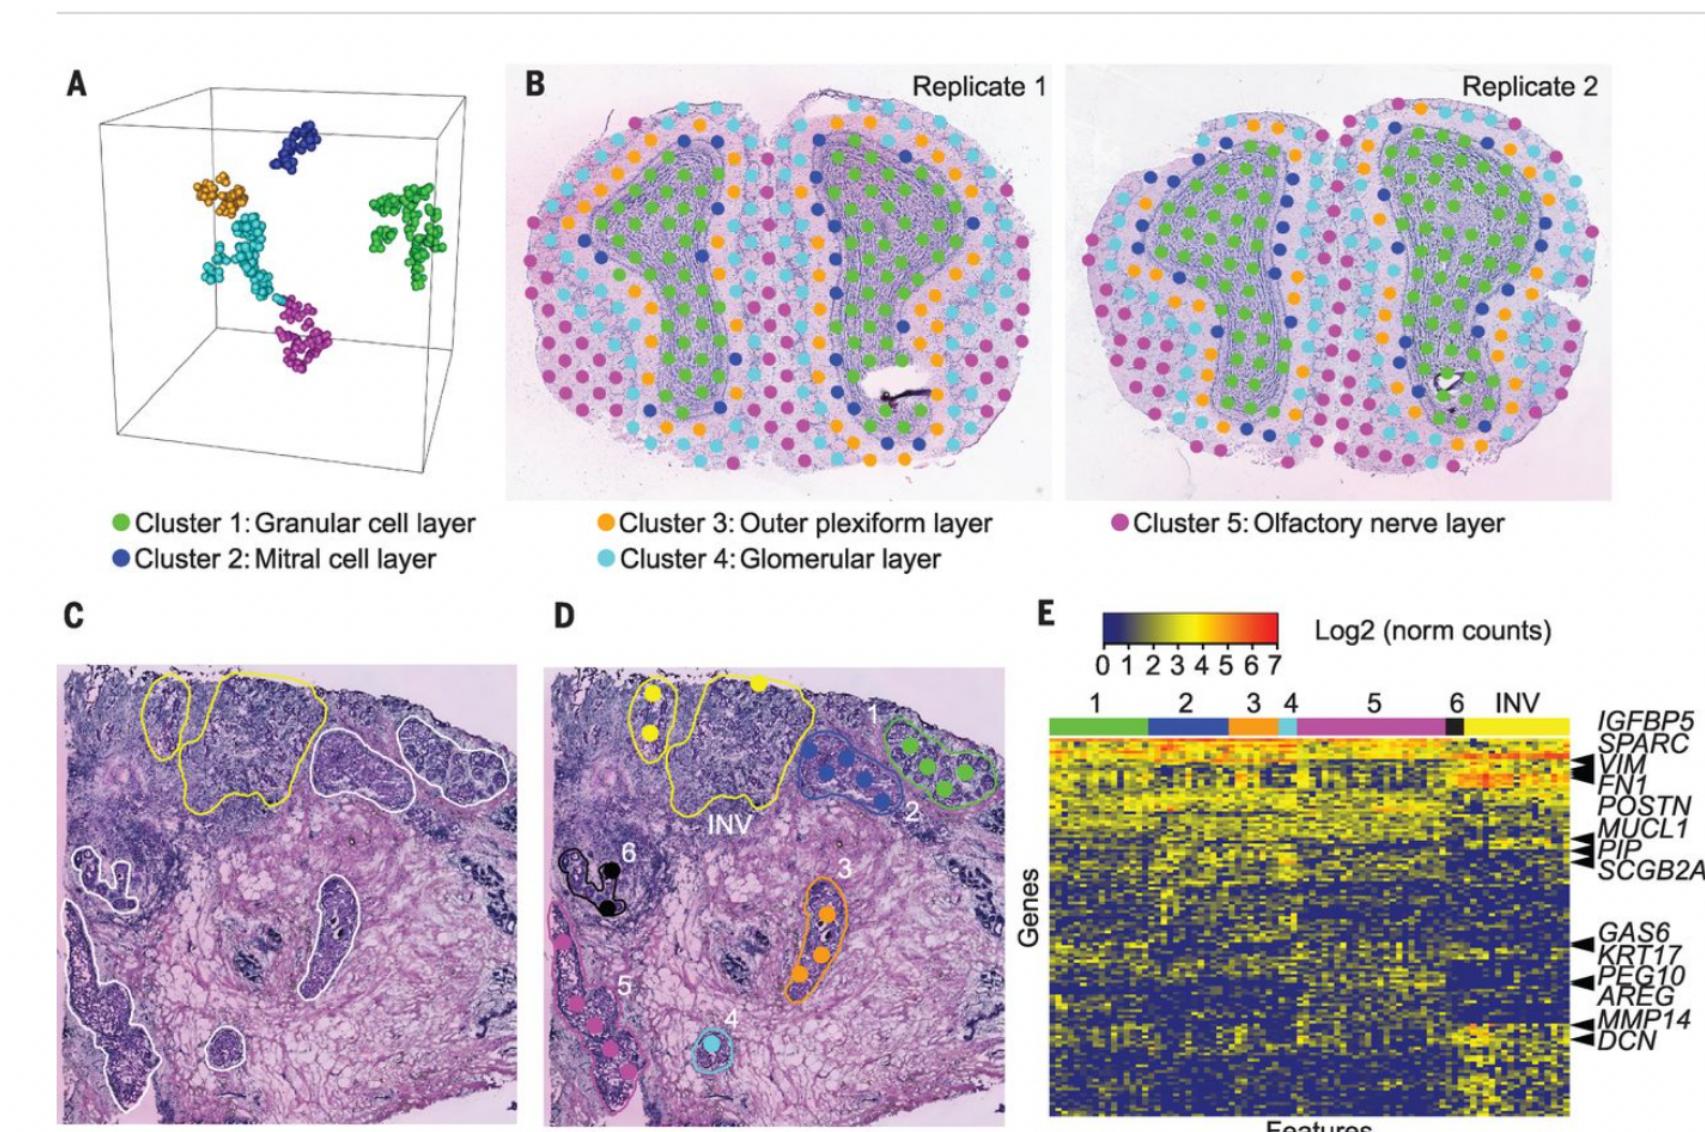

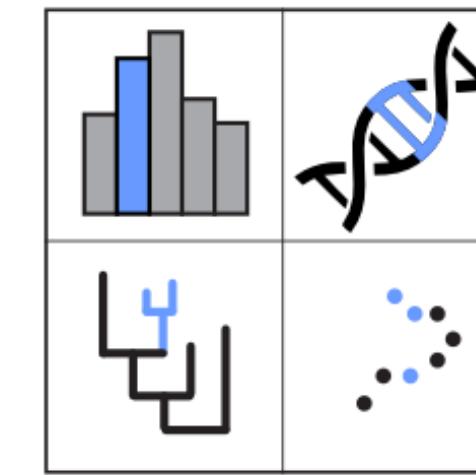

Fig. 4 Comparative analyses of tissue domains. (A) t-SNE analysis and hierarchical clustering of 551 features from two replicates creates five distinct clusters. (B) The features placed back onto the two tissue images. (C and D) Histological section of a breast cancer biopsy (C) containing invasive ductal cancer (INV) and six separate areas of ductal cancer in situ (1 to 6), with analyzed spatial transcriptomics features in (D). INV areas without, or with minimal, stromal infiltration were selected. (E) Gene expression heat map over the different areas in four adjacent sections (D) and (fig. S11).

Data Decoupage with glue

Alyssa Goodman, Center for Astrophysics | Harvard & Smithsonian

GORDON AND BETTY
MOORE
FOUNDATION

 The Jackson
Laboratory

glue
solutions
inc.

Collage and **decoupage** are both paper crafts involving cutting and gluing. They both take **images, photos and materials from one source and turn them into something completely different**. However, they are not one and the same. **Collage** is considered a formal **art**, while **decoupage** is considered a **craft**.

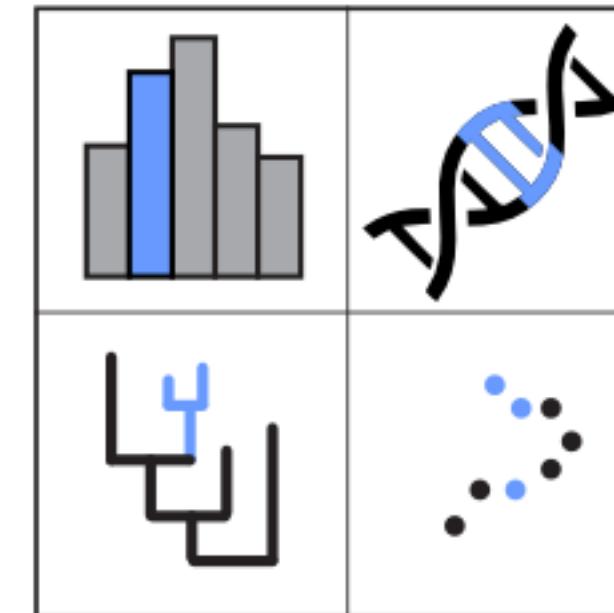

Collage has been around for hundreds, if not thousands, of years, with some believing its earliest forms were found in 200 B.C. China. The art form was not always referred to as collage, in fact coinage of the term is attributed to Pablo Picasso in the early 20th century. **The word **collage** comes from the French word **coller**, which means to **glue****. The fine art community agrees that collage as an art form began in the early 20th century as part of modernism. A mixed-media or photo collage is a work of art, meant to be framed and admired.

Decoupage, on the other hand, comes from the French word decouper, which means to cut out. In this craft, a surface is covered with glued paper cut-outs.

Due to its decorative nature, **the decoupage crafter must take extra steps to protect** the surface once the decorations have been applied and **glued**.

Cells to Genes and Back Again

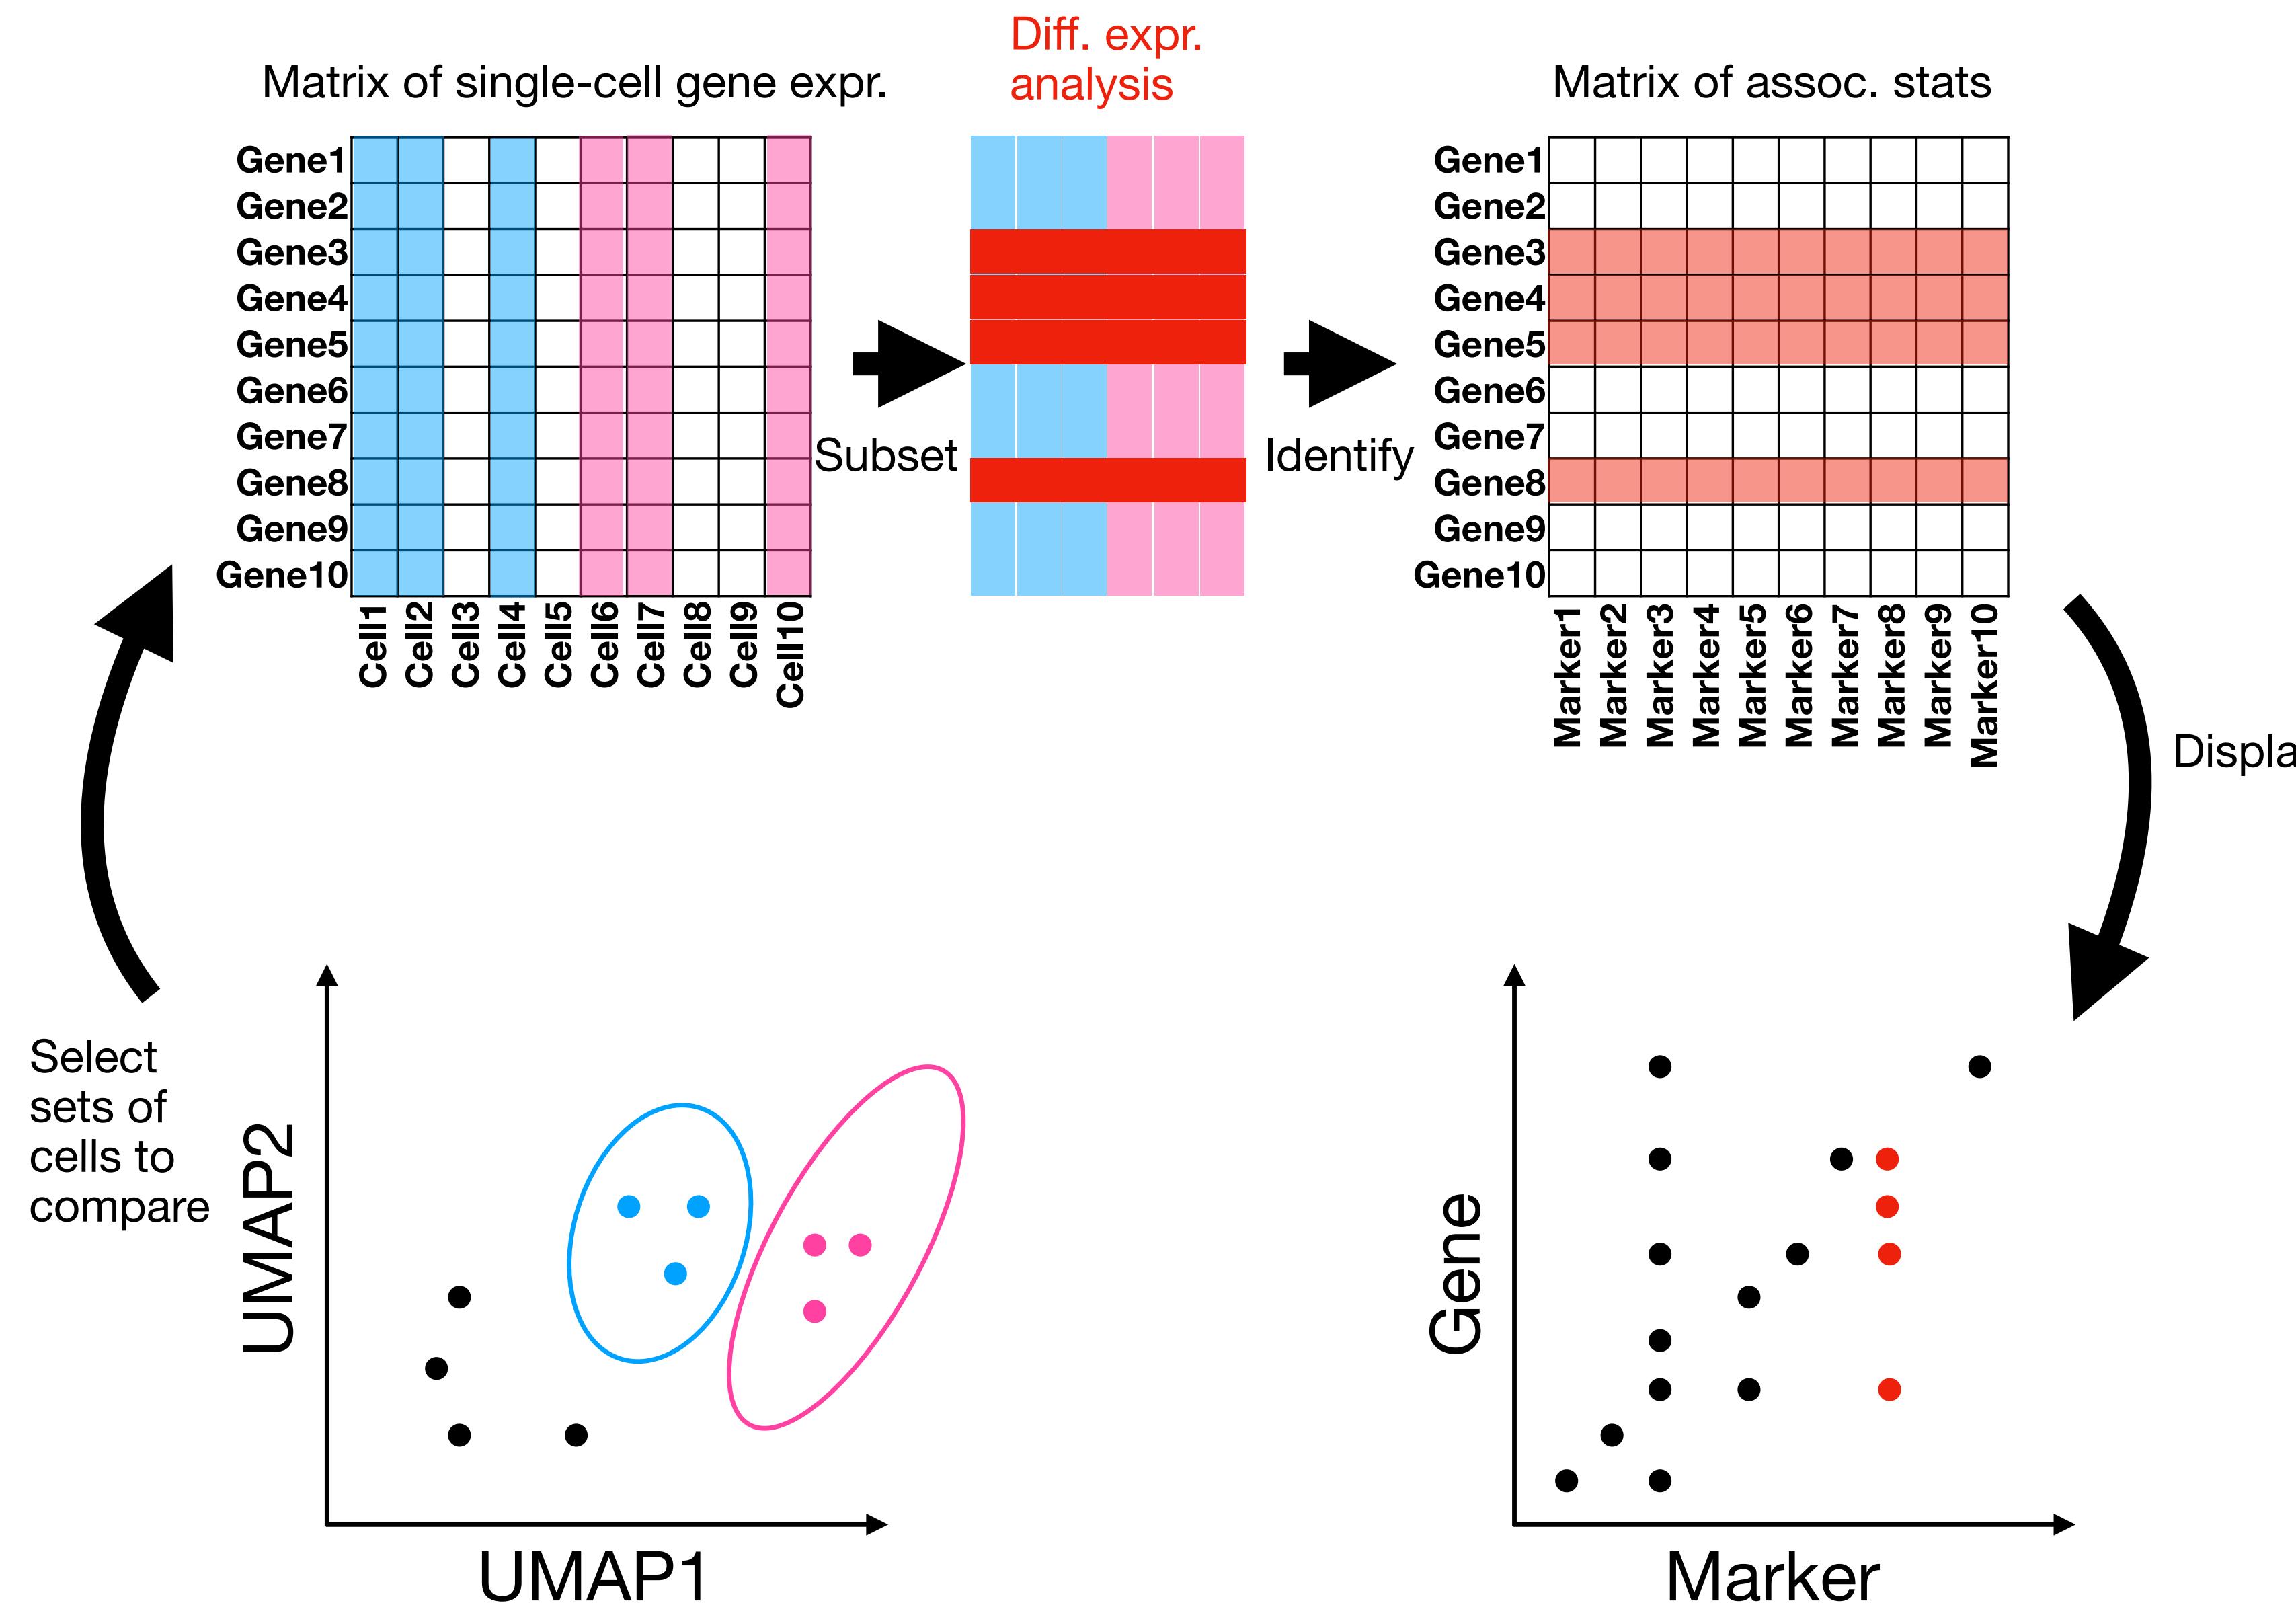

Using **glue genes** for single cell exploratory data analysis

glue
genes

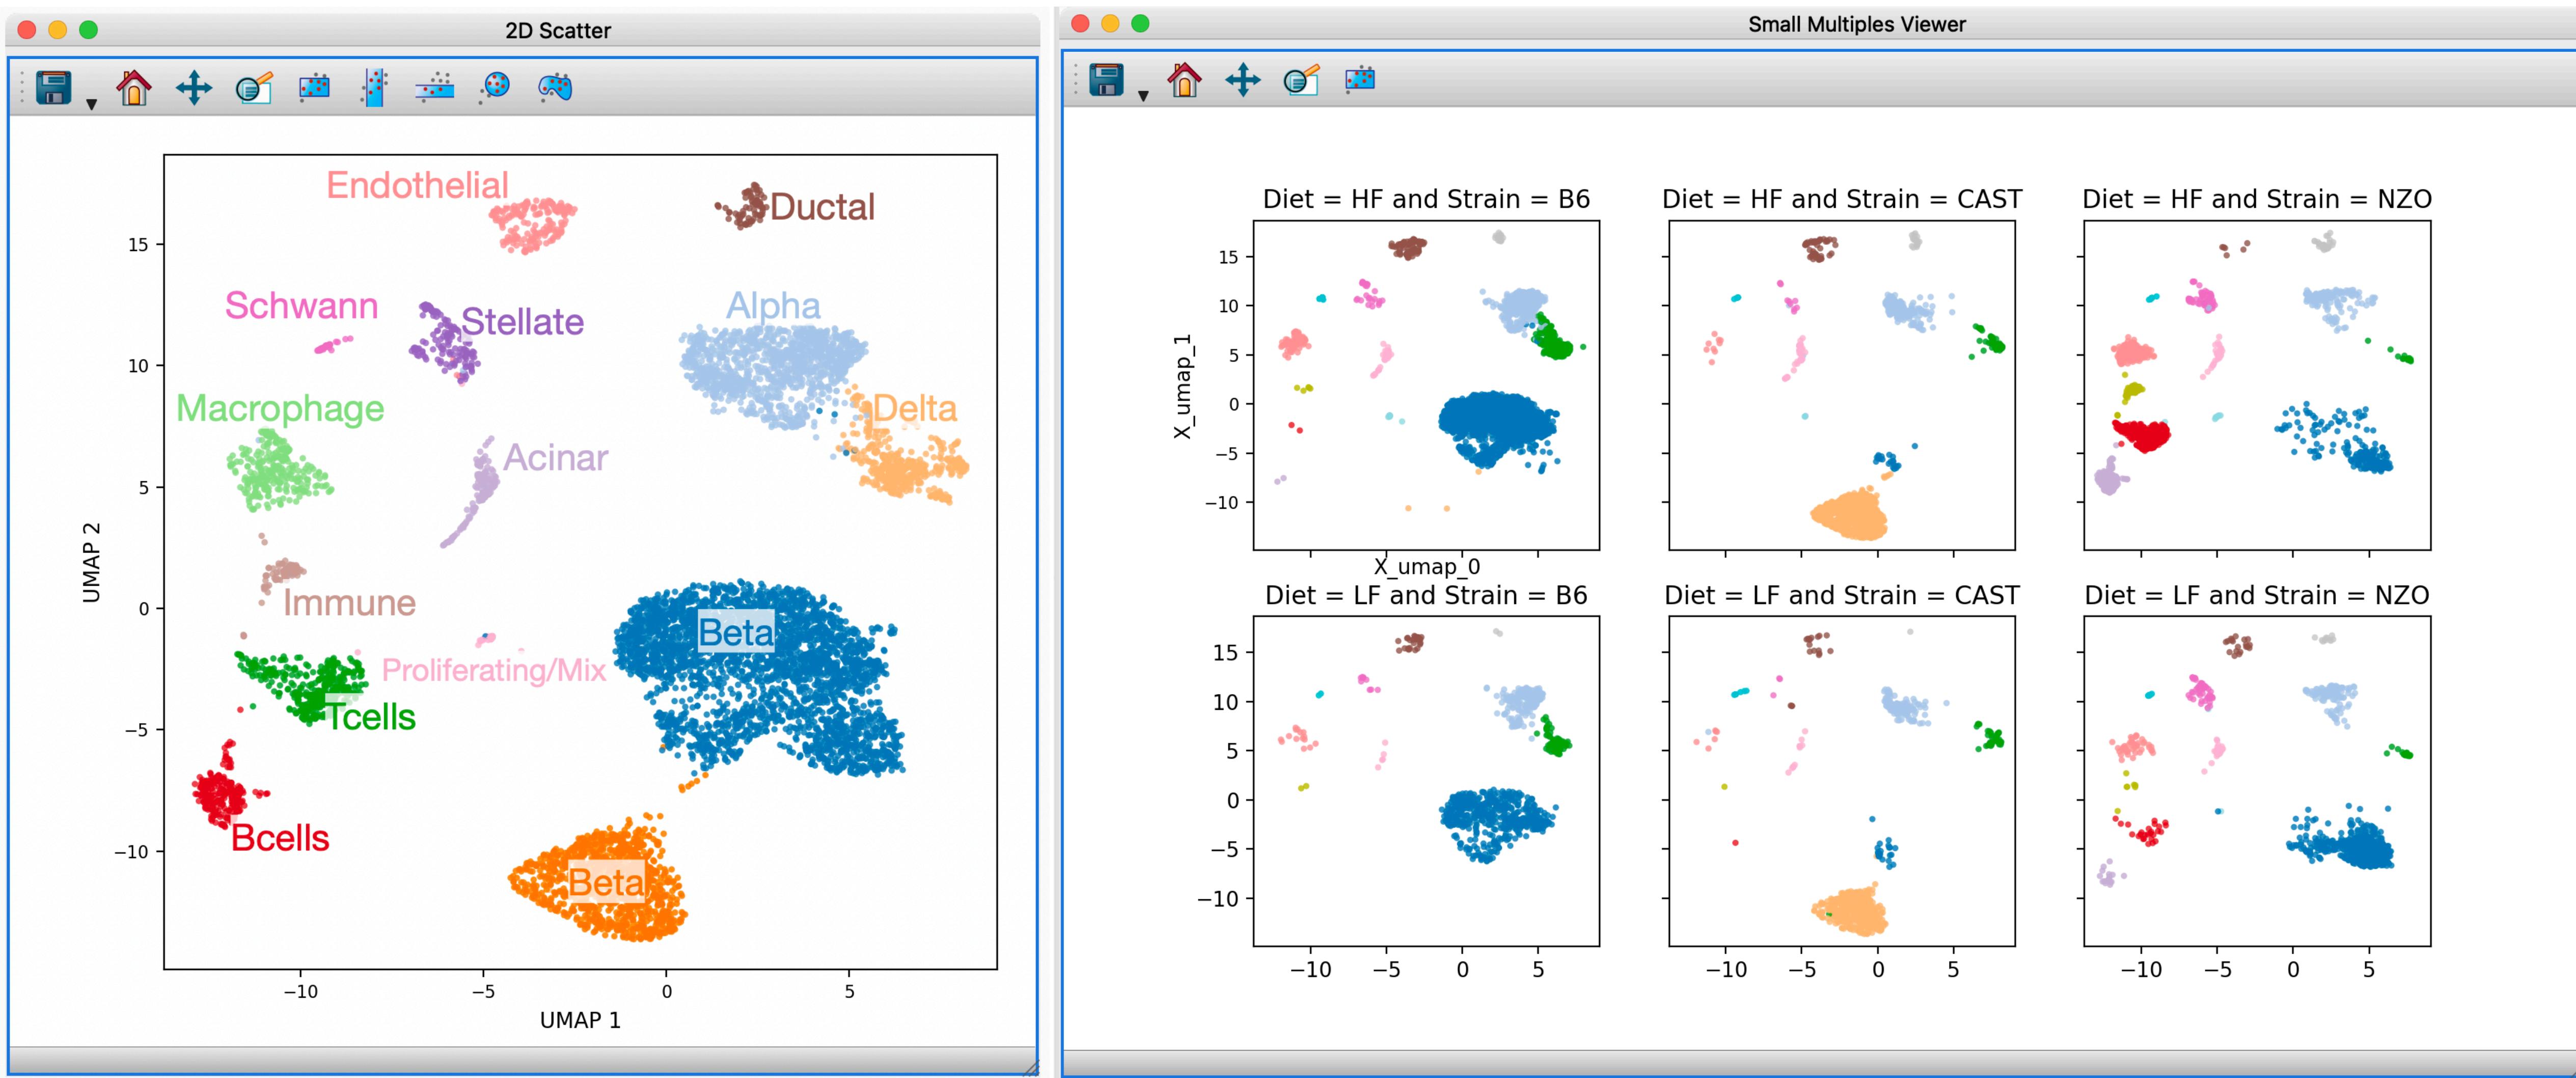

(slides from) Jonathan Foster, CTO, glue solutions, inc.

Cells to Genes

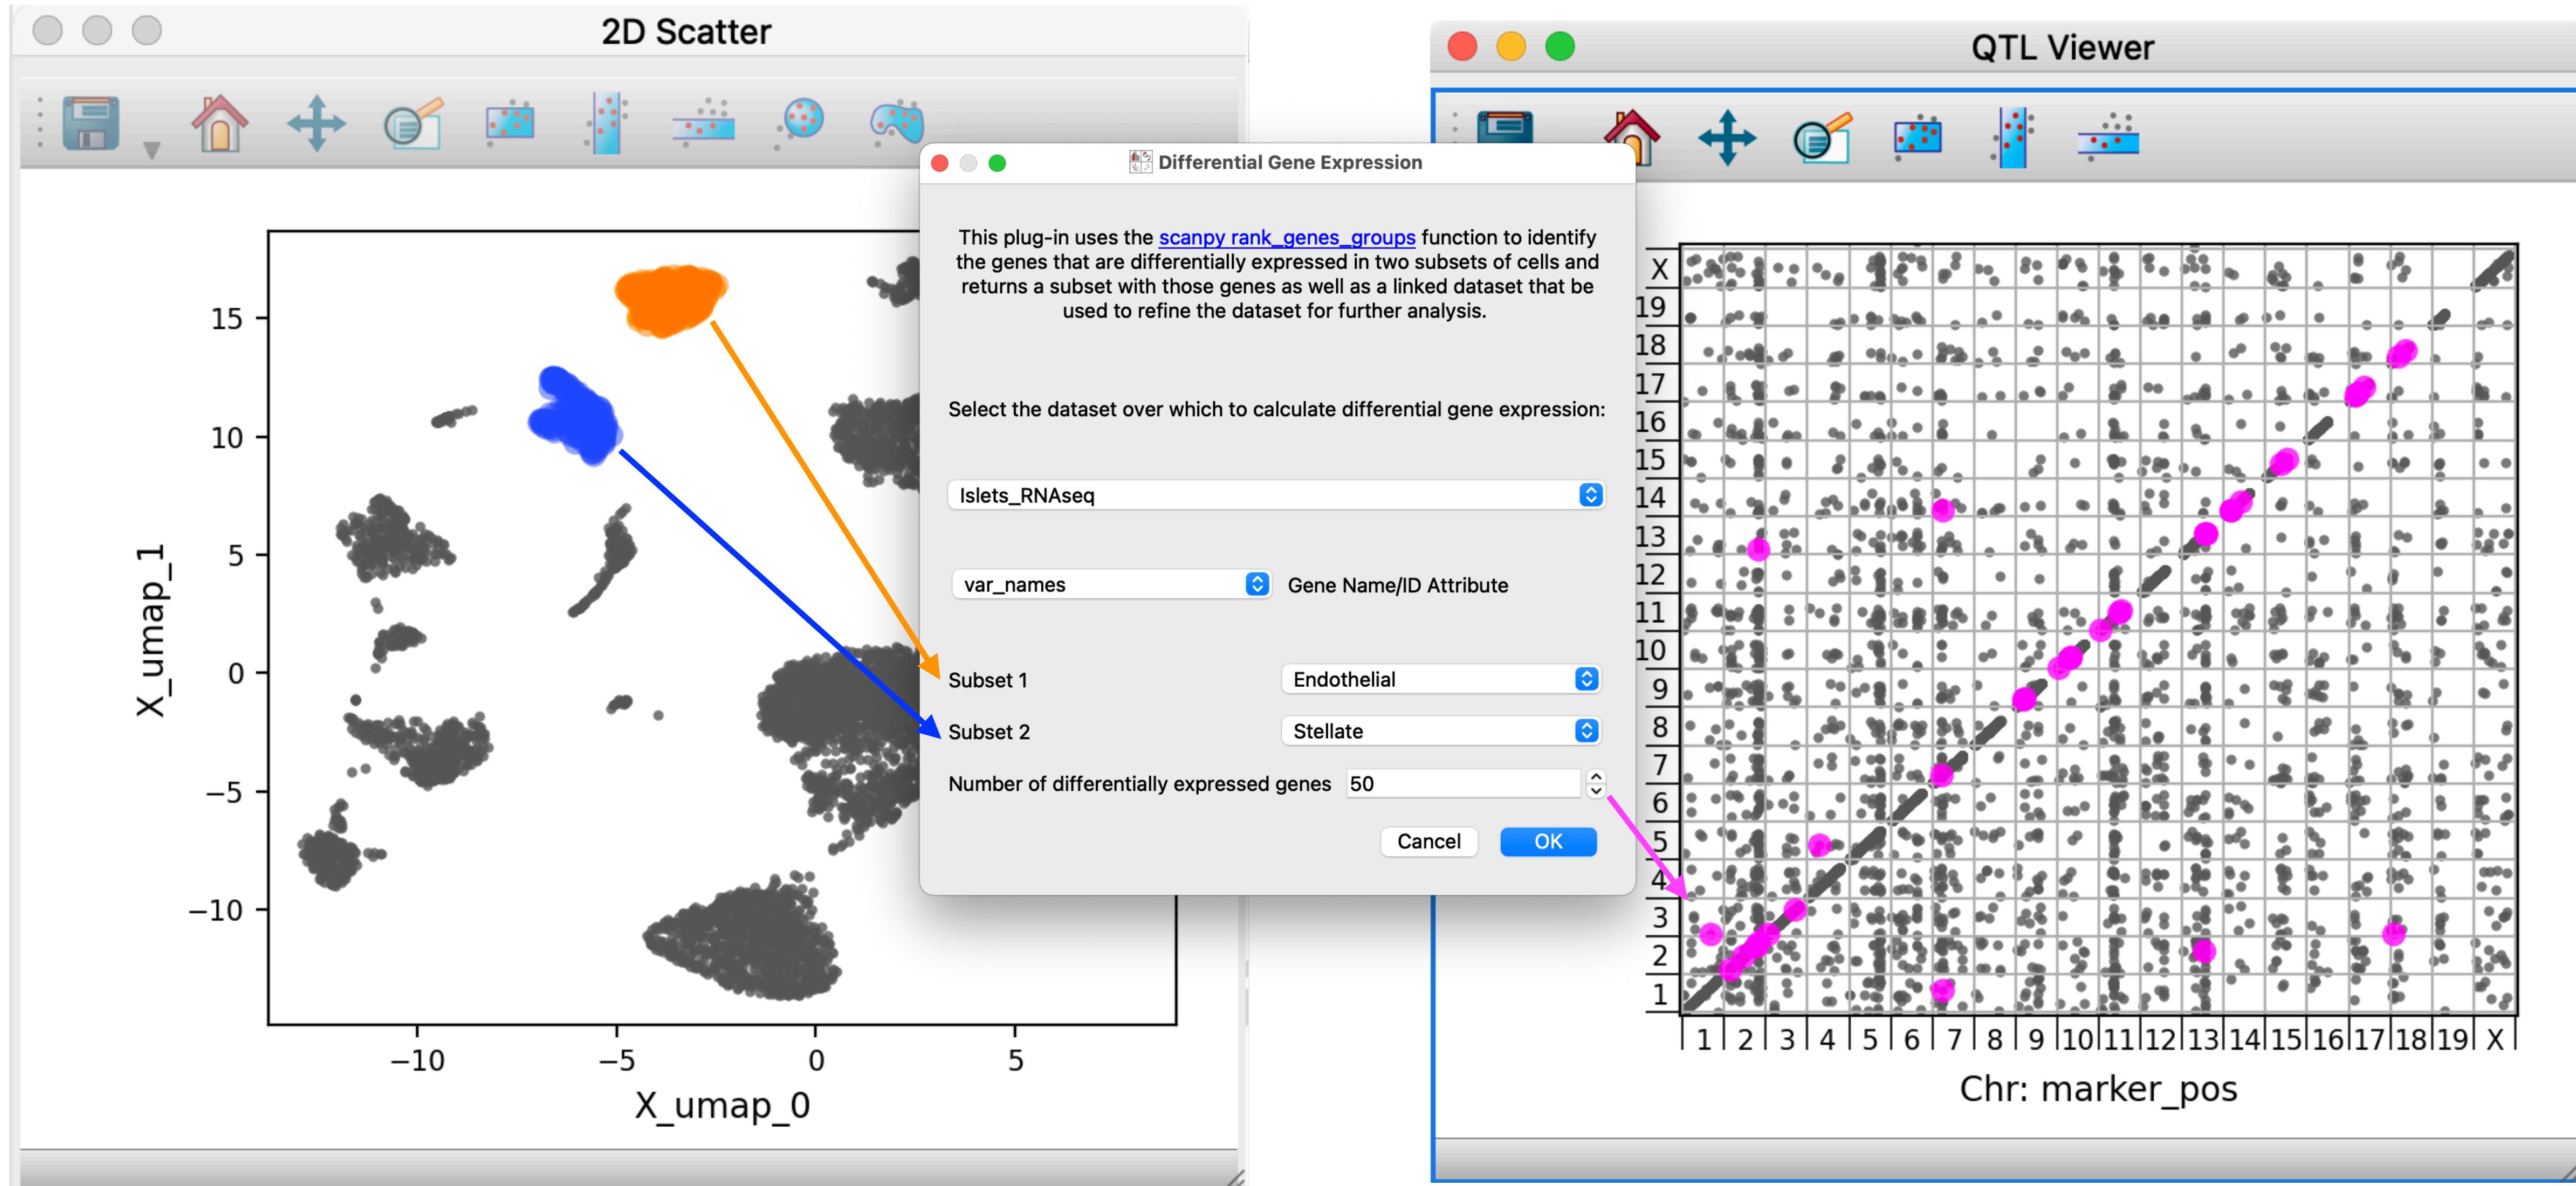

From ChatGPT: A gene is a specific sequence of DNA that carries instructions for creating proteins or functional RNA molecules, while a **marker** is a specific DNA sequence used as a reference point to identify the presence or absence of a gene or genetic variation without directly contributing to the production of proteins or RNA molecules

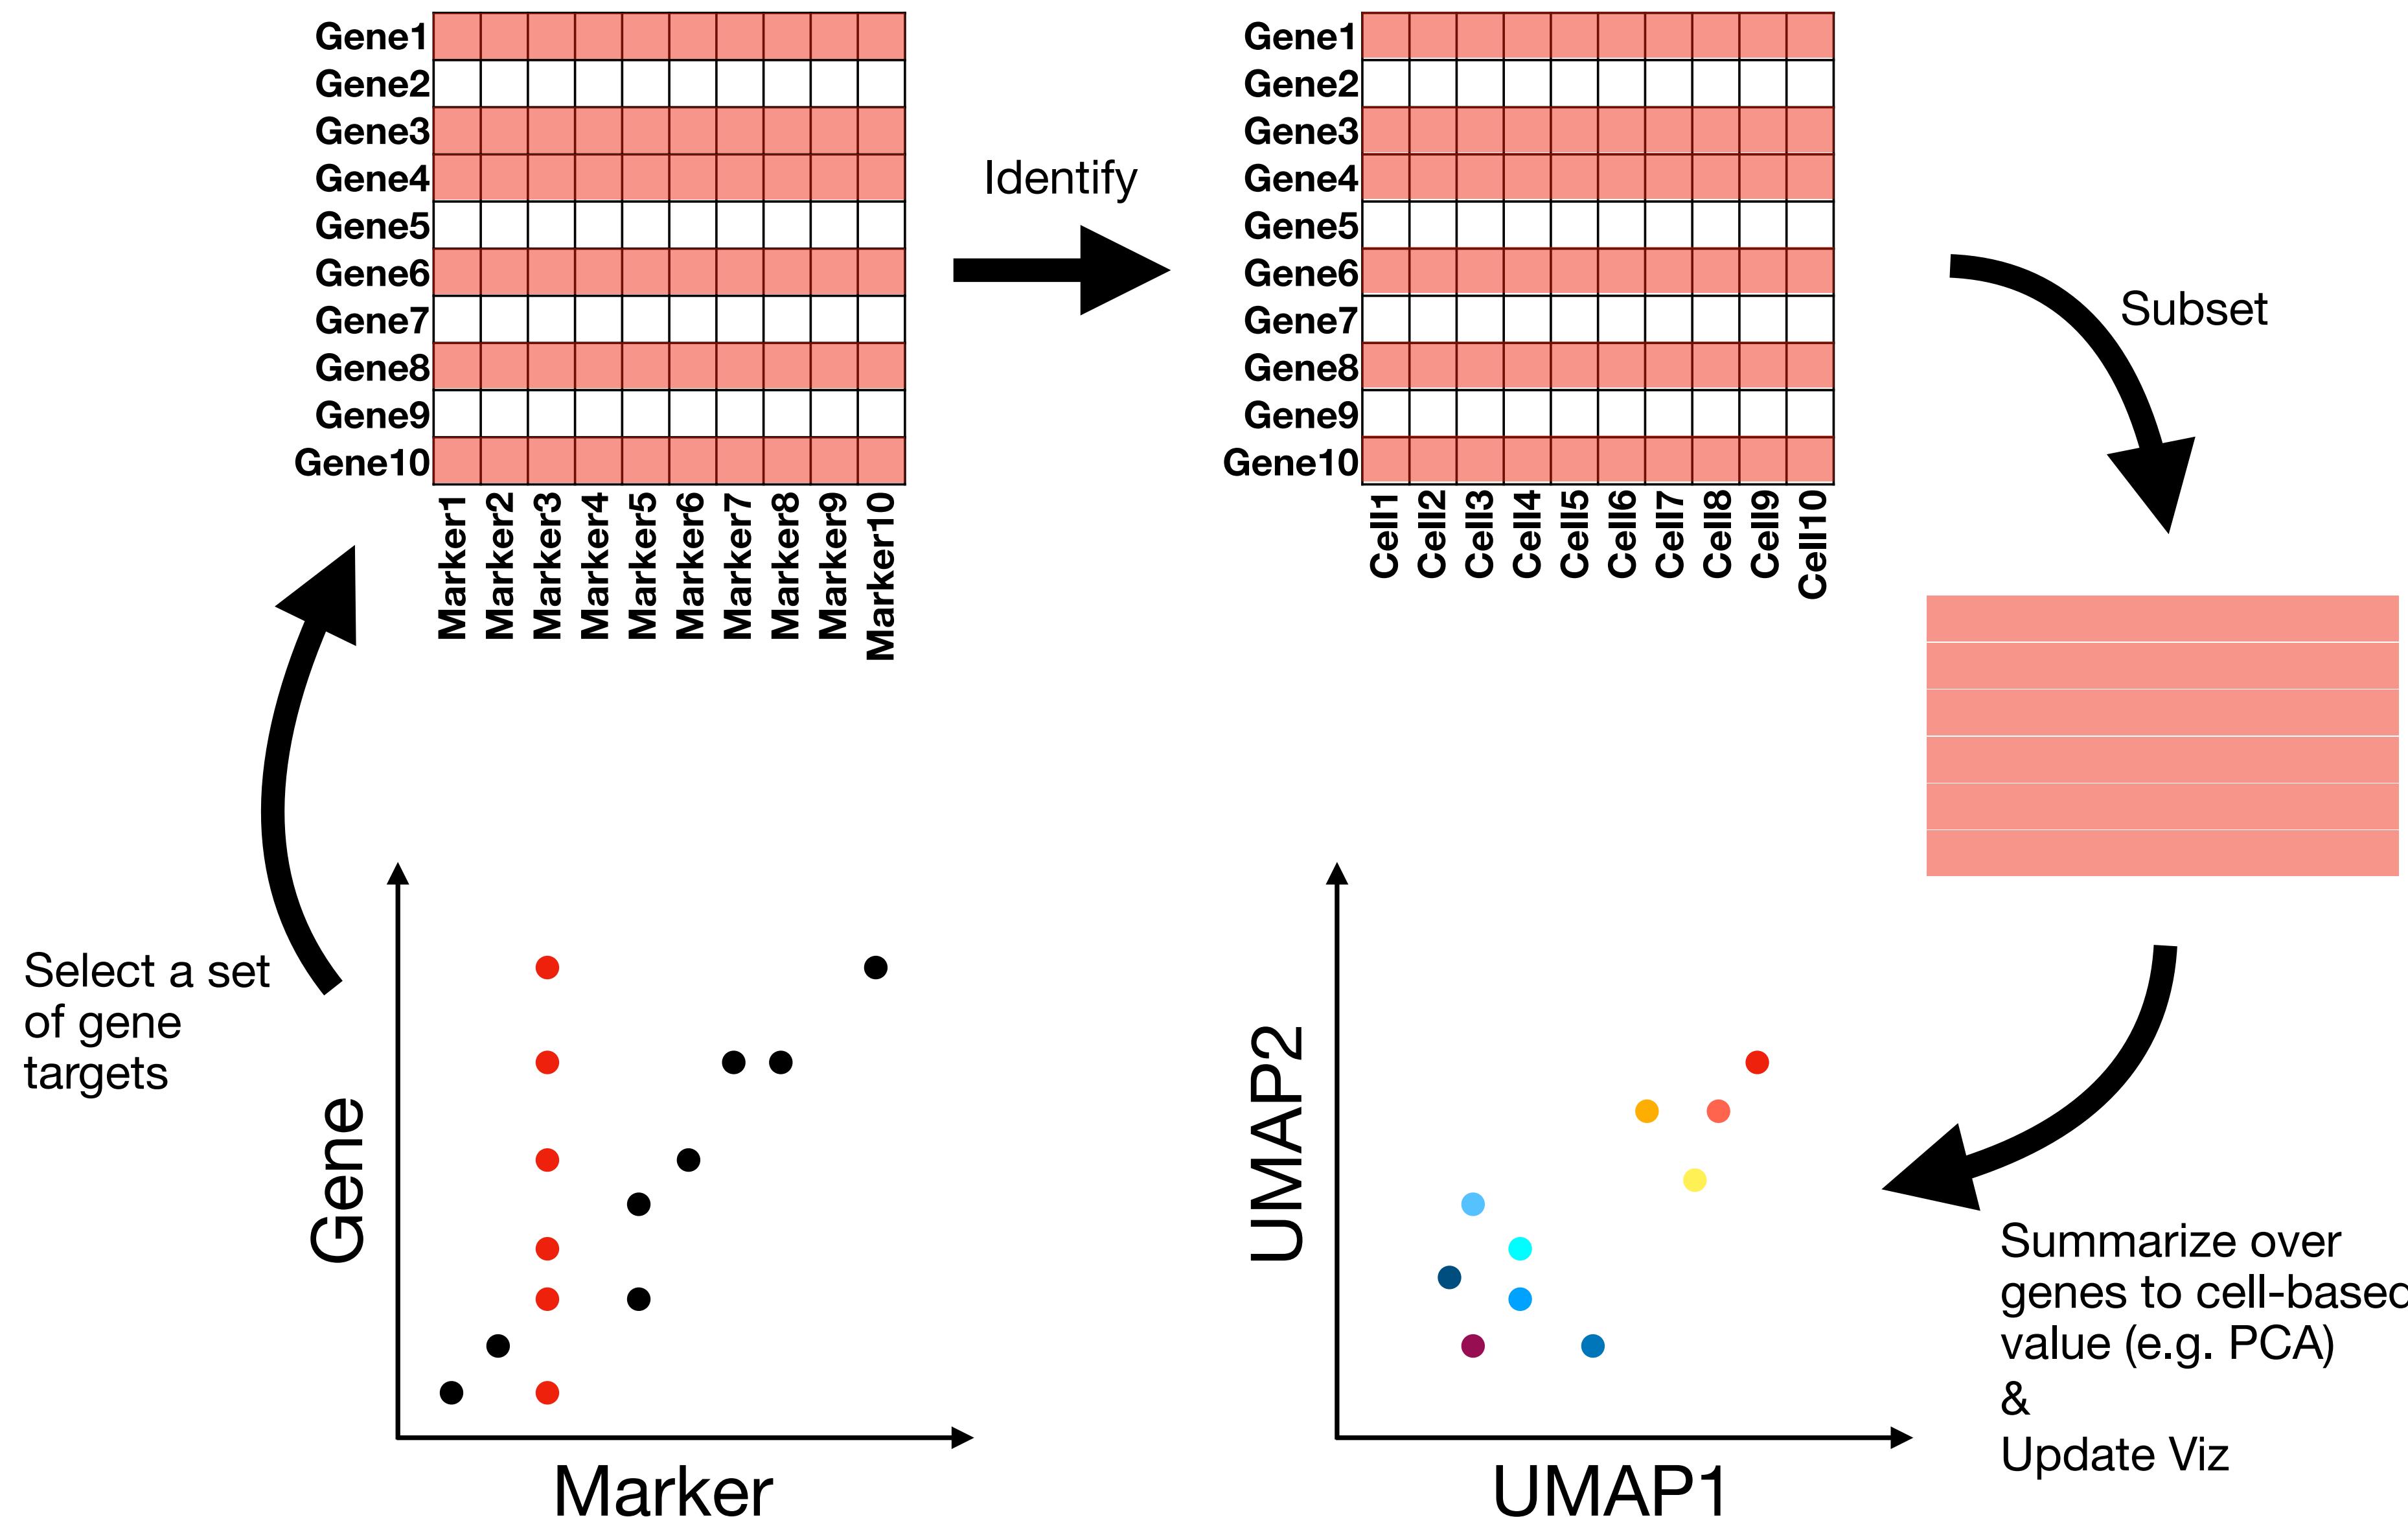

Display cell properties over experimental factors
