PERSEUS c. 1918

BLACK & WHITE MONOCHROME IMAGE

*Photograph by E. E. Barnard*

# PERSEUS c. 1980s-2006

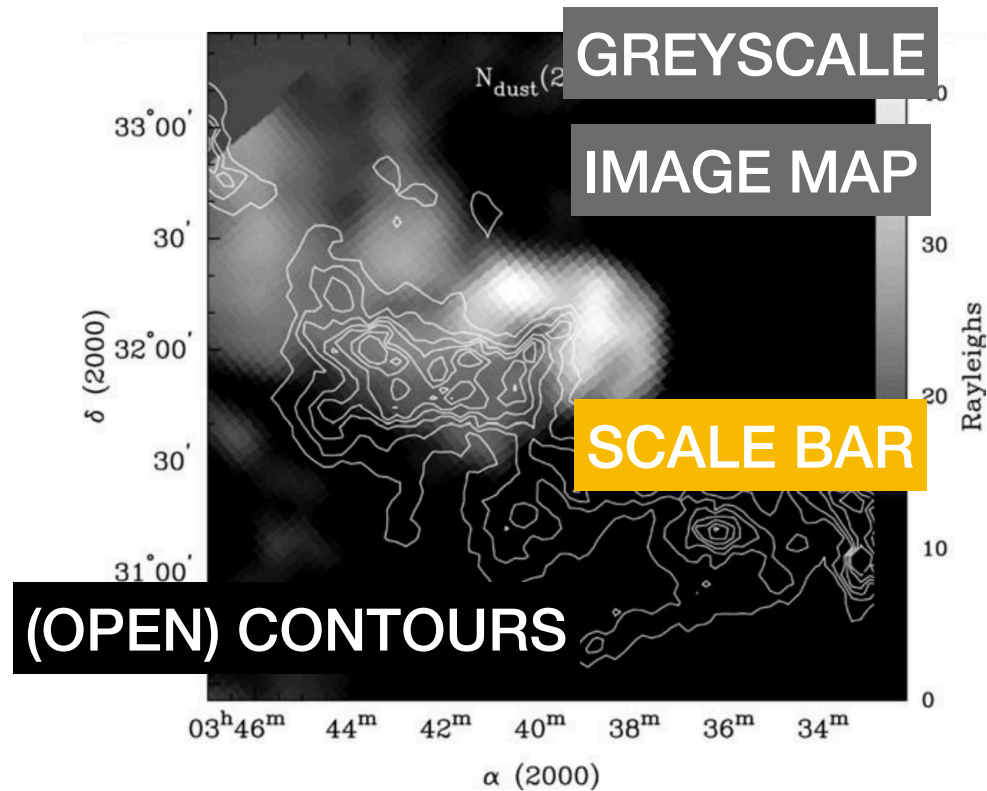

Figure 2. An  $H\alpha$  image of G159.6-18.5 from Finkbeiner (2003) overlaid on extinction contours derived from 2MASS/NICER (from Ridge et al. 2006a). The  $H\alpha$  image shows the  $1.2^\circ$  diameter diffuse HII region G159.6-18.5 located behind the Perseus molecular cloud and ionized by the O9.5 / B0.5 star HD 278942.

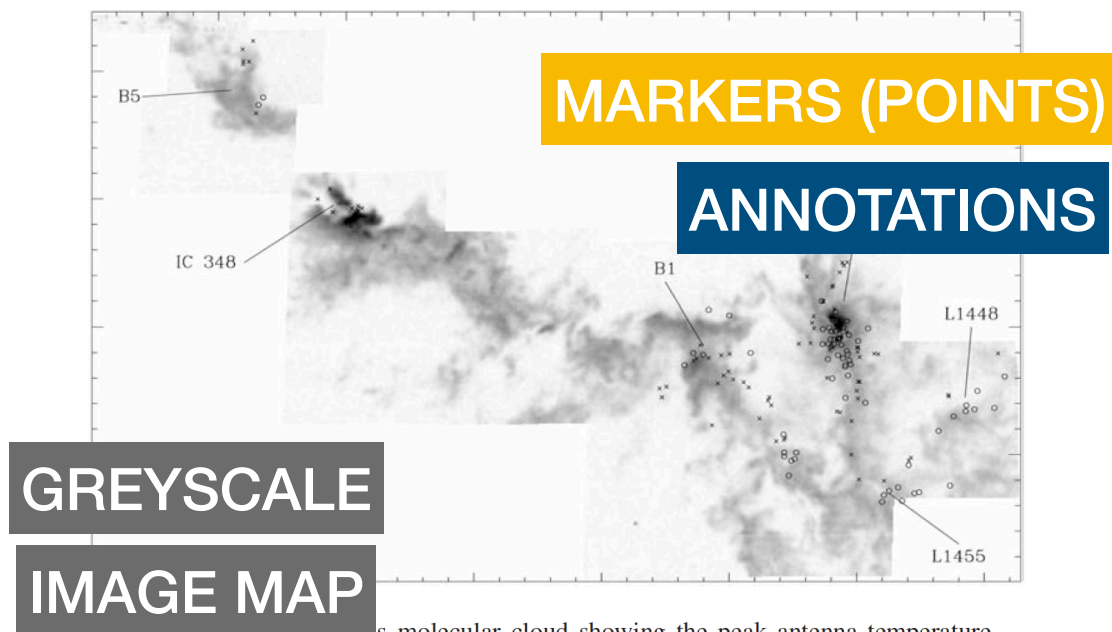

Figure 6. The Perseus molecular cloud showing the peak antenna temperature of the 110 GHz  $J = 1 - 0$  transition of  $^{13}\text{CO}$ . The circles show Herbig-Haro objects discovered prior to the Mosaic CCD survey of  $H\alpha$  and  $[\text{SII}]$  emission by Walawender et al. (2005a). The crosses show the new objects found in the Mosaic survey.

Figure 3. A visual wavelength image of the Perseus molecular cloud. This image was obtained by Adam Block.

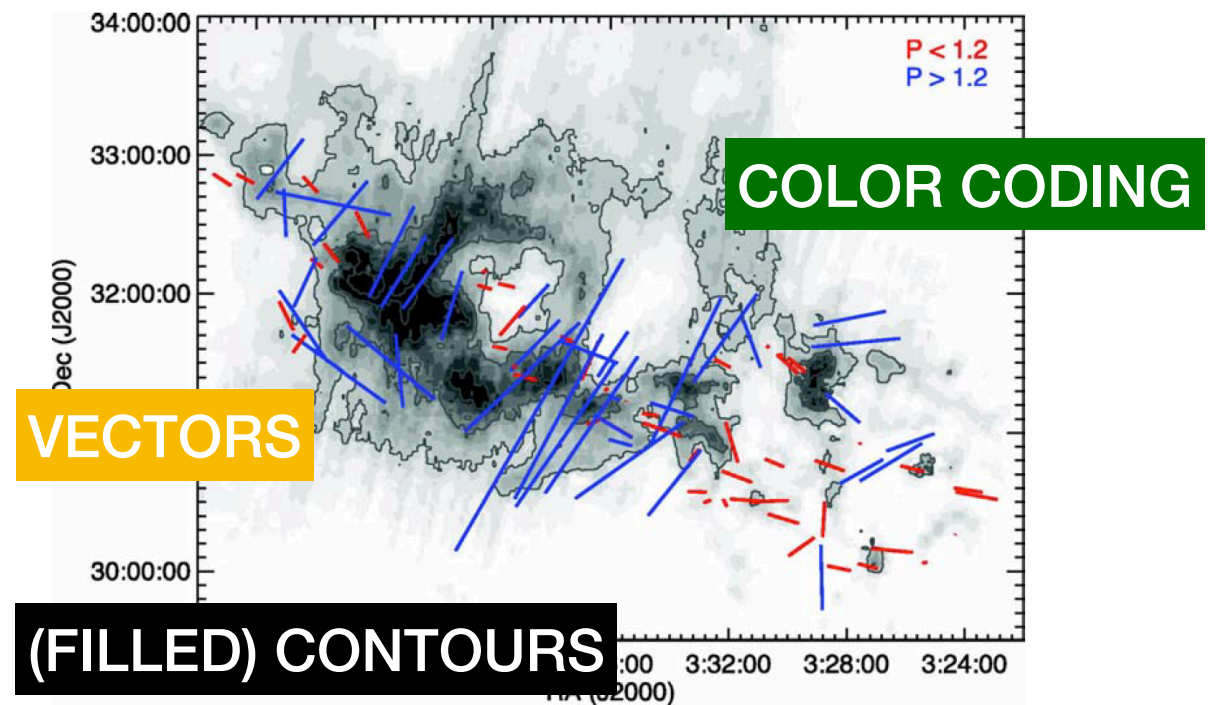

Figure 7. IRAS-derived dust column density overlaid with polarization vectors from Goodman et al. (1990). The polarization vectors shown are parallel to the orientation of the magnetic field in the plane of the sky. Blue vectors have polarization strength  $P > 1.2\%$  and red vectors have  $P < 1.2\%$ . The stronger polarization may trace warm dust associated with the IRAS dust (courtesy of the COMPLETE team).

of key physical properties associated with volumes bounded by iso-surfaces, such as radius ( $R$ ), velocity dispersion ( $\sigma_v$ ) and luminosity ( $L$ ). The volumes can have any shape, and in our work<sup>†</sup> we focus on the significance of the especially elongated features seen in L1448 (Fig. 2a). The luminosity is an approximated figure for mass, such that  $M_{\text{gas}} = X_{\text{HCO}} \chi_{\text{HCO}}$ , where  $X_{\text{HCO}} = 8.0 \times 10^{-6} \text{ cm}^3 \text{ km}^{-1} \text{ s}^{-1}$  (ref. 15; see Supplementary Methods and Supplementary Figure 2). The derived values for size, mass and velocity dispersion can then be used to estimate the role of self-gravity at each point in the hierarchy, via calculation of an 'observed' virial parameter,  $z_{\text{obs}} = 5 \sigma_v^2 R / (GM_{\text{gas}})$ . In principle, extended portions of the tree (Fig. 2, yellow highlighting)

2D GRAPH

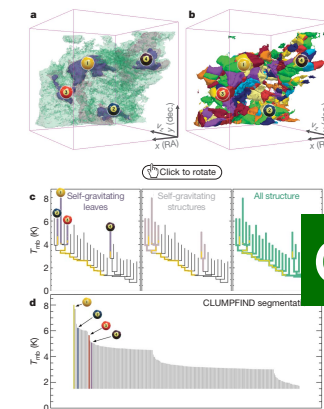

Figure 2 | Comparison of the 'dendrogram' and 'CLUMPFIND' feature-identification algorithms as applied to  $^{13}\text{CO}$  emission from the L1448 region of Perseus. a, 3D visualization of the surfaces indicated by colours in the dendrogram shown in c. Purple illustrates the smallest scale self-gravitating structures in the region corresponding to the leaves of the dendrogram; pink shows the smallest surfaces that contain distinct self-gravitating leaves within them; and green corresponds to the surface in data cube containing all the significant emission. Dendrogram branches corresponding to self-gravitating objects have been highlighted in yellow over the range of  $T_{\text{mb}}$  (main-beam temperature) test-level values for which the virial parameter is less than 2. The x-y locations of the four 'self-gravitating' leaves labelled with billiard balls are the same as those shown in Fig. 1. The 3D visualizations show position-position-velocity ( $p$ - $p$ - $v$ ) space. RA, right ascension; dec., declination. For comparison with the ability of dendrograms (c) to track hierarchical structure, d shows a pseudo-dendrogram of the CLUMPFIND segmentation (b), with the same four labels used in Fig. 1 and in a. As 'clumps' are not allowed to belong to larger structures, each pseudo-branch in d is simply a series of lines connecting the maximum emission value in each clump to the threshold value. A very large number of clumps appears in b because of the sensitivity of CLUMPFIND to noise and small-scale structure in the data. In the online PDF version, the 3D cubes (a and b) can be rotated to any orientation, and surfaces can be turned on and off (interaction requires Adobe Acrobat version 7.0.8 or higher). In the printed version, the front face of each 3D cube (the 'home' view in the interactive online version) corresponds exactly to the patch of sky shown in Fig. 1, and velocity with respect to the Local Standard of Rest increases from front ( $-0.5 \text{ km s}^{-1}$ ) to back ( $8 \text{ km s}^{-1}$ ).

data, CLUMPFIND typically finds features on a limited range of scales, above but close to the physical resolution of the data, and its results can be overly dependent on input parameters. By tuning CLUMPFIND's two free parameters, the same molecular-line data set<sup>4</sup> can be used to show either that the frequency distribution of clump mass is the same as the initial mass function of stars or that it follows the much shallower mass function associated with large-scale molecular clouds (Supplementary Fig. 1).

Four years before the advent of CLUMPFIND, 'structure trees' were proposed as a way to characterize clouds' hierarchical structure

using 2D maps of column density. With this early 2D work as inspiration, we have developed a structure-identification algorithm that abstracts the hierarchical structure of a 3D ( $p$ - $p$ - $v$ ) data cube into an easily visualized representation called a 'dendrogram'. Although well developed in other data-intensive fields<sup>11,12</sup>, it is curious that the application of tree methodologies so far in astrophysics has been rare, and almost exclusively within the area of galaxy evolution, where 'merger trees' are being used with increasing frequency<sup>13</sup>.

Figure 3 and its legend explain the construction of dendrograms schematically. The dendrogram quantifies how and where local maxima of emission merge with each other, and its implementation is explained in Supplementary Methods. Critically, the dendrogram is determined almost entirely by the data itself, and it has negligible sensitivity to algorithm parameters. To make graphical presentation possible on paper and 2D screens, we 'flatten' the dendrograms of 3D

of key physical properties associated with volumes bounded by iso-surfaces, such as radius ( $R$ ), velocity dispersion ( $\sigma_v$ ) and luminosity ( $L$ ). The volumes can have any shape, and in other work<sup>14</sup> we focus on the significance of the especially elongated features seen in L1448 (Fig. 2a). The luminosity is an approximate proxy for mass, such that  $M_{\text{lum}} = X_{\text{HCO}} L_{\text{HCO}}$ , where  $X_{\text{HCO}} = 8.0 \times 10^{-9} \text{ cm}^{-2} \text{ K}^{-1} \text{ km}^{-1} \text{ s}$  (ref. 15; see Supplementary Methods and Supplementary Fig. 2). The derived values for size, mass and velocity dispersion can then be used to estimate the role of self-gravity at each point in the hierarchy, via calculation of an 'observed' virial parameter,  $\alpha_{\text{obs}} = 5\sigma_v^2 R / G M_{\text{lum}}$ . In principle, extended portions of the tree (Fig. 2, yellow highlighting)

Figure 3 | Schematic illustration of the dendrogram process. Shown is the construction of a dendrogram from a hypothetical one-dimensional emission profile (black). The dendrogram (blue) can be constructed by 'drowning' a test constant emission level (horizontal) from above in five steps (examples are 1, 2, 3, 4, 5). The dendrogram shows how local maxima merge into larger structures. The dendrogram is a hierarchical tree structure that represents the merging of local maxima of emission. The dendrogram is a hierarchical tree structure that represents the merging of local maxima of emission. The dendrogram is a hierarchical tree structure that represents the merging of local maxima of emission.

For comparison with the ability of dendrograms (**c**) to track hierarchical structure, **d** shows a pseudo-dendrogram of the CLUMPFIND segmentation (**b**), with the same four labels used in Fig. 1 and in **a**. As 'clumps' are not allowed to belong to larger structures, each pseudo-branch in **d** is simply a series of lines connecting the maximum emission value in each clump to the threshold value. A very large number of clumps appears in **b** because of the sensitivity of CLUMPFIND to noise and small-scale structure in the data. In the online PDF version, the 3D cubes (**a** and **b**) can be rotated to any orientation, and surfaces can be turned on and off (interaction requires Adobe Acrobat version 7.0.8 or higher). In the printed version, the front face of each 3D cube (the 'home' view in the interactive online version) corresponds exactly to the patch of sky shown in Fig. 1, and velocity with respect to the Local Standard of Rest increases from front ( $-0.5 \text{ km s}^{-1}$ ) to back ( $8 \text{ km s}^{-1}$ ).

data, CLUMPFIND typically finds features on a limited range of scales, above but close to the physical resolution of the data, and its results can be overly dependent on input parameters. By tuning CLUMPFIND's two free parameters, the same molecular-line data set<sup>8</sup> can be used to show either that the frequency distribution of clump mass is the same as the initial mass function associated with large-scale molecular clouds (Supplementary Fig. 1).

Four years before the advent of CLUMPFIND, 'structure trees'<sup>9</sup> were proposed as a way to characterize clouds' hierarchical structure

maps of column density. With the help of 2D work as inspiration, we have developed a structure-identification algorithm that abstracts the hierarchical structure of a data cube into an easily visualized representation called a 'dendrogram'. This application of tree methodologies so far has been almost exclusively within the astronomical community, where 'merger trees' are being used with increasing frequency. Figure 3 and its legend explain the algorithm schematically. The dendrogram and

BUT—these are “dead” panels! That's not good enough.

## ANNOTATIONS

**Figure 3 | Schematic of dendrogram construction.** Shown is the construction of a dendrogram from a hypothetical one-dimensional emission profile (black). The dendrogram (blue) can be constructed by 'dropping' a test constant emission level (purple) from above in tiny steps (exaggerated in size here, light lines) until all the local maxima and mergers are found, and connected as shown. The intersection of a test level with the emission is a set of points (for example the light purple dots) in one dimension, a planar curve in two dimensions, and an isosurface in three dimensions. The dendrogram of 3D data shown in Fig. 2c is the direct analogue of the tree shown here, only constructed from 'isosurface' rather than 'point' intersections. It has been sorted and flattened for representation on a flat page, as fully representing dendrograms for 3D data cubes would require four dimensions.

## LETTERS

### A role for self-gravity at multiple length scales in the process of star formation

Alyssa A. Goodman<sup>1,2</sup>, Erik W. Rosolowsky<sup>2,3</sup>, Michelle A. Borkin<sup>1†</sup>, Jonathan B. Foster<sup>2</sup>, Michael Halle<sup>1,4</sup>, Jens Kauffmann<sup>1,2</sup> & Jaime E. Pineda<sup>2</sup>

Self-gravity plays a decisive role in the final stages of star formation, where dense cores (size  $\sim 0.1$  parsecs) inside molecular clouds collapse to form star-plus-disk systems<sup>1</sup>. But self-gravity's role at earlier times (and on larger length scales, such as  $\sim 1$  parsec) is unclear; some molecular cloud simulations that do not include self-gravity suggest that ‘turbulent fragmentation’ alone is sufficient to create a mass distribution of dense cores that resembles, and sets, the stellar initial mass function<sup>2</sup>. Here we report a ‘dendrogram’ (hierarchical tree-diagram) analysis that reveals that self-gravity plays a significant role over the full range of possible scales traced by  $^{13}\text{CO}$  observations in the L1448 molecular cloud, but not everywhere in the observed region. In particular, more than 90 per cent of the compact ‘pre-stellar cores’ traced by peaks of dust emission<sup>3</sup> are projected on the sky within one of the dendrogram's self-gravitating ‘leaves’. As these peaks mark the locations of already-forming stars, or of those probably about to form, a self-gravitating cocoon seems a critical condition for their exist-

overlapping features as an option, significant emission found between prominent clumps is typically either appended to the nearest clump or turned into a small, usually ‘pathological’, feature needed to encompass all the emission being modelled. When applied to molecular-line

AUGMENTED REALITY(!)

**Elements: Enriching Scholarly Communication with Augmented Reality**  
 INTELLECTUAL MERIT

Augmented reality (AR<sup>1</sup>) technology has crossed a usability threshold that makes it timely to embed it in scholarly communication.

The technology an astrophysicist uses to buy furniture should not be better than what she can use to communicate science. Fifteen years ago, contextualizing virtual objects like the chair in the AR-generated image [2] in Figure 1 required specialized, expensive, and often cumbersome (Figure 2) hardware [3]. But, in the last few years, thanks in large part to significant investment by companies like Apple and Google, AR is now mainstream, easy-to-use, and free, with just a smartphone or tablet [4].
